### 3.19 MSRs - MSR0000\_XXXX

See 3.1 [Register Descriptions and Mnemonics] for a description of the register naming convention. MSRs are accessed through x86 WRMSR and RDMSR instructions.

#### MSR0000\_0000 Load-Store MCA Address

| Bits | Description                             |
|------|-----------------------------------------|
| 63:0 | Alias of <a href="#">MSR0000_0402</a> . |

#### MSR0000\_0001 Load-Store MCA Status

| Bits | Description                             |
|------|-----------------------------------------|
| 63:0 | Alias of <a href="#">MSR0000_0401</a> . |

#### MSR0000\_0010 Time Stamp Counter (TSC)

Reset: 0000\_0000\_0000\_0000h.

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 63:32 | <b>TSC[63:32]: time stamp counter high.</b> See: TSC[31:0].                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 31:0  | <b>TSC[31:0]: time stamp counter low.</b> Read-write; updated-by-hardware. TSC[63:0] = {TSC[63:32], TSC[31:0]}. The TSC increments at the P0 frequency. This field uses software P-state numbering. See 2.5.3.1.1.1 [Software P-state Numbering]. The TSC counts at the same rate in all P-states, all C states, S0, or S1. A read of this MSR in guest mode is affected by <a href="#">MSRC000_0104 [Time Stamp Counter Ratio (TscRateMsr)]</a> . The value (TSC/TSCRatio) is the TSC P0 frequency based value (as if TSCRatio==1.0) when (TSCRatio!=1.0). |

#### MSR0000\_001B APIC Base Address (APIC\_BAR)

| Bits  | Description                                                                                                                                                                                                             |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 63:40 | MBZ.                                                                                                                                                                                                                    |
| 39:12 | <b>ApicBar[39:12]: APIC base address register.</b> Read-write. Reset: 00_FEE0_0h. Specifies the base address, physical address [39:12], for the APICXX register set in xAPIC mode. See 2.4.9.1.2 [APIC Register Space]. |
| 11    | <b>ApicEn: APIC enable.</b> Read-write. Reset: 0. See 2.4.9.1.2 [APIC Register Space]. 1=Local APIC is enabled in xAPIC mode.                                                                                           |
| 10    | MBZ.                                                                                                                                                                                                                    |
| 9     | MBZ.                                                                                                                                                                                                                    |
| 8     | <b>BSC: boot strap core.</b> Read-write; updated-by-hardware. Reset: x. 1=The core is the boot core of the BSP. 0=The core is not the boot core of the BSP.                                                             |
| 7:0   | MBZ.                                                                                                                                                                                                                    |

**MSR0000\_002A Cluster ID (EBL\_CR\_POWERON)**

Read; GP-write. Writes to this register result in a GP fault with error code 0.

| Bits  | Description                                                        |
|-------|--------------------------------------------------------------------|
| 63:18 | MBZ.                                                               |
| 17:16 | <b>ClusterID</b> . Reset: 00b. The field does not affect hardware. |
| 15:0  | MBZ.                                                               |

**MSR0000\_00E7 Max Performance Frequency Clock Count (MPERF)**

Reset: 0000\_0000\_0000\_0000h.

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 63:0 | <b>MPERF: maximum core clocks counter</b> . Read-write; <a href="#">Updated-by-hardware</a> . Incremented by hardware at the P0 frequency while the core is in C0. This register does not increment when the core is in the stop-grant state. In combination with <a href="#">MSR0000_00E8</a> , this is used to determine the effective frequency of the core. A read of this MSR in guest mode is affected by <a href="#">MSRC000_0104 [Time Stamp Counter Ratio (TscRateMsr)]</a> . This field uses software P-state numbering. See <a href="#">MSRC001_0015[Eff-FreqCntMwait]</a> , <a href="#">2.5.3.3 [Effective Frequency]</a> , and <a href="#">2.5.3.1.1.1 [Software P-state Numbering]</a> . |

**MSR0000\_00E8 Actual Performance Frequency Clock Count (APERF)**

Reset: 0000\_0000\_0000\_0000h.

| Bits | Description                                                                                                                                                                                                                                                                                                          |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 63:0 | <b>APERF: actual core clocks counter</b> . Read-write; <a href="#">Updated-by-hardware</a> . This register increments in proportion to the actual number of core clocks cycles while the core is in C0. The register does not increment when the core is in the stop-grant state. See <a href="#">MSR0000_00E7</a> . |

**MSR0000\_00FE MTRR Capabilities (MTRRcap)**

Read; GP-write. Reset: 0000\_0000\_0000\_0508h.

| Bits  | Description                                                                                            |
|-------|--------------------------------------------------------------------------------------------------------|
| 63:11 | Reserved.                                                                                              |
| 10    | <b>MtrrCapWc: write-combining memory type</b> . 1=The write combining memory type is supported.        |
| 9     | Reserved.                                                                                              |
| 8     | <b>MtrrCapFix: fixed range register</b> . 1=Fixed MTRRs are supported.                                 |
| 7:0   | <b>MtrrCapVCnt: variable range registers count</b> . Specifies the number of variable MTRRs supported. |

**MSR0000\_0174 SYSENTER CS (SYSENTER\_CS)**

| Bits  | Description |
|-------|-------------|
| 63:32 | RAZ.        |

|       |                                                                                                           |
|-------|-----------------------------------------------------------------------------------------------------------|
| 31:16 | Reserved.                                                                                                 |
| 15:0  | <b>SysEnterCS: SYSENTER target CS.</b> Read-write. Reset: 0000h. Holds the called procedure code segment. |

#### MSR0000\_0175 SYSENTER ESP (SYSENTER\_ESP)

Reset: 0000\_0000\_0000\_0000h.

| Bits  | Description                                                                                   |
|-------|-----------------------------------------------------------------------------------------------|
| 63:32 | Reserved.                                                                                     |
| 31:0  | <b>SysEnterESP: SYSENTER target SP.</b> Read-write. Holds the called procedure stack pointer. |

#### MSR0000\_0176 SYSENTER EIP (SYSENTER\_EIP)

Reset: 0000\_0000\_0000\_0000h.

| Bits  | Description                                                                                         |
|-------|-----------------------------------------------------------------------------------------------------|
| 63:32 | Reserved.                                                                                           |
| 31:0  | <b>SysEnterEIP: SYSENTER target IP.</b> Read-write. Holds the called procedure instruction pointer. |

#### MSR0000\_0179 Global Machine Check Capabilities (MCG\_CAP)

Read; GP-write.

| Bits | Description                                                                                                                                                                                   |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 63:9 | Reserved.                                                                                                                                                                                     |
| 8    | <b>McgCtlP: MCG_CTL register present.</b> Value: 1. 1=The machine check control registers (MCI_CTL) are present. See <a href="#">2.15.1 [Machine Check Architecture]</a>                      |
| 7:0  | <b>Count.</b> Value: 07h. Indicates the number of error reporting banks visible to each core. 06h=Error-reporting banks 0 through 5. See <a href="#">2.15.1.1 [Machine Check Registers]</a> . |

#### MSR0000\_017A Global Machine Check Status (MCG\_STAT)

Reset: 0000\_0000\_0000\_0000h. See [2.15.1 \[Machine Check Architecture\]](#).

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 63:3 | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 2    | <b>MCIP: machine check in progress.</b> Read-write; set-by-hardware. 1=A machine check is in progress.                                                                                                                                                                                                                                                                                                                                   |
| 1    | <b>EIPV: error instruction pointer valid.</b> Read-write; Updated-by-hardware. 1=The instruction pointer that was pushed onto the stack by the machine check mechanism references the instruction that caused the machine check error.                                                                                                                                                                                                   |
| 0    | <b>RIPV: restart instruction pointer valid.</b> Read-write; Updated-by-hardware. 1=Program execution can be reliably restarted at the EIP address on the stack. 0=The interrupt was not precise and/or the process (task) context may be corrupt; continued operation of this process may not be possible without intervention, however system processing or other processes may be able to continue with appropriate software clean up. |

**MSR0000\_017B Global Machine Check Exception Reporting Control (MCG\_CTL)**

Read-write. Reset: 0000\_0000\_0000\_0000h. This registers controls enablement of the individual error reporting banks; see 2.15.1 [Machine Check Architecture]. When a machine check register bank is not enabled in MCG\_CTL, errors for that bank are not logged or reported, and actions enabled through the MCA are not taken; each MCi\_CTL register identifies which errors are still corrected when MCG\_CTL[i] is disabled.

| Bits | Description                                                                                                         |
|------|---------------------------------------------------------------------------------------------------------------------|
| 63:7 | Unused.                                                                                                             |
| 6    | <b>MC6En: MC6 register bank enable.</b> 1=The MC6 machine check register bank is enabled.                           |
| 5    | <b>MC5En: MC5 register bank enable.</b> 1=The MC5 machine check register bank is enabled.                           |
| 4    | <b>MC4En: MC4 register bank enable.</b> 1=The MC4 machine check register bank is enabled for all cores of the node. |
| 3    | Unused.                                                                                                             |
| 2    | <b>MC2En: MC2 register bank enable.</b> 1=The MC2 machine check register bank is enabled.                           |
| 1    | <b>MC1En: MC1 register bank enable.</b> 1=The MC1 machine check register bank is enabled.                           |
| 0    | <b>MC0En: MC0 register bank enable.</b> 1=The MC0 machine check register bank is enabled.                           |

**MSR0000\_01D9 Debug Control (DBG\_CTL\_MSR)**

| Bits | Description                                                                                                 |
|------|-------------------------------------------------------------------------------------------------------------|
| 63:7 | Reserved.                                                                                                   |
| 6    | MBZ.                                                                                                        |
| 5:2  | <b>PB: performance monitor pin control.</b> Read-write. Reset: 0. This field does not control any hardware. |
| 1    | <b>BTF.</b> Read-write. Reset: 0. 1=Enable branch single step.                                              |
| 0    | <b>LBR.</b> Read-write. Reset: 0. 1=Enable last branch record.                                              |

**MSR0000\_01DB Last Branch From IP (BR\_FROM)**

Read; GP-write; *Not-same-for-all*, *Updated-by-hardware*. Reset: 0000\_0000\_0000\_0000h.

| Bits | Description                                                                        |
|------|------------------------------------------------------------------------------------|
| 63:0 | <b>LastBranchFromIP.</b> Loaded with the segment offset of the branch instruction. |

**MSR0000\_01DC Last Branch To IP (BR\_TO)**

Read; GP-write; *Not-same-for-all*, *Updated-by-hardware*. Reset: 0000\_0000\_0000\_0000h.

| Bits | Description                                                                                                    |
|------|----------------------------------------------------------------------------------------------------------------|
| 63:0 | <b>LastBranchToIP.</b> Holds the target RIP of the last branch that occurred before an exception or interrupt. |

**MSR0000\_01DD Last Exception From IP**

Read; GP-write; [Not-same-for-all](#), [Updated-by-hardware](#). Reset: 0000\_0000\_0000\_0000h.

| Bits | Description                                                                                                     |
|------|-----------------------------------------------------------------------------------------------------------------|
| 63:0 | <b>LastIntFromIP</b> . Holds the source RIP of the last branch that occurred before the exception or interrupt. |

**MSR0000\_01DE Last Exception To IP**

Read; GP-write; [Not-same-for-all](#), [Updated-by-hardware](#). Reset: 0000\_0000\_0000\_0000h.

| Bits | Description                                                                                                   |
|------|---------------------------------------------------------------------------------------------------------------|
| 63:0 | <b>LastIntToIP</b> . Holds the target RIP of the last branch that occurred before the exception or interrupt. |

**MSR0000\_020[F:0] Variable-Size MTRRs Base/Mask**

[Per-compute-unit](#).

Each MTRR ([MSR0000\\_020\[F:0\] \[Variable-Size MTRRs Base/Mask\]](#), [MSR0000\\_02\[6F:68,59:58,50\]](#), or [MSR0000\\_02FF \[MTRR Default Memory Type \(MTRRdefType\)\]](#)) specifies a physical address range and a corresponding memory type (MemType) associated with that range. Setting the memory type to an unsupported value results in a #GP.

The variable-size MTRRs come in pairs of base and mask registers ([MSR0000\\_0200](#) and [MSR0000\\_0201](#) are the first pair, etc.). Variables MTRRs are enabled through [MSR0000\\_02FF\[MtrrDefTypeEn\]](#). A core access--with address CPUAddr--is determined to be within the address range of a variable-size MTRR if the following equation is true:

$\text{CPUAddr}[39:12] \& \text{PhyMask}[39:12] == \text{PhyBase}[39:12] \& \text{PhyMask}[39:12]$ .

For example, if the variable MTRR spans 256 KB and starts at the 1 MB address. The PhyBase would be set to 0\_0010\_0000h and the PhyMask to F\_FFFC\_0000h (with zeros filling in for bits[11:0]). This results in a range from 0\_0010\_0000h to 0\_0013\_FFFF.

**MSR0000\_020[E,C,A,8,6,4,2,0] Variable-Size MTRRs Base**

Table 215: [Register Mapping](#) for [MSR0000\\_020\[E,C,A,8,6,4,2,0\]](#)

| Register     | Function |
|--------------|----------|
| MSR0000_0200 | Range 0  |
| MSR0000_0202 | Range 1  |
| MSR0000_0204 | Range 2  |
| MSR0000_0206 | Range 3  |
| MSR0000_0208 | Range 4  |
| MSR0000_020A | Range 5  |
| MSR0000_020C | Range 6  |
| MSR0000_020E | Range 7  |

**Table 216: Valid Values** for Memory Type Definition

| Bits      | Description            |
|-----------|------------------------|
| 000b      | UC or uncacheable.     |

**MSR0000\_02[6F:68,59:58,50] Fixed-Size MTRRs**

[Per-compute-unit.](#)

See [MSR0000\\_020\[F:0\]](#) for general MTRR information. Fixed MTRRs are enabled through [MSR0000\\_02FF](#)[MtrrDefTypeFixEn, MtrrDefTypeEn]. For addresses below 1MB, the appropriate Fixed

MTRRs override the default access destination. Each fixed MTRR includes two bits, RdDram and WrDram, that determine the destination based on the access type.

See 2.4.6.1.2 [Determining The Access Destination for Core Accesses].

### MSR0000\_0277 Page Attribute Table (PAT)

This register specifies the memory type based on the PAT, PCD, and PWT bits in the virtual address page tables.

| Bits  | Description                                                                                   |

#### MSR0000\_0401 MC0 Machine Check Status (MC0\_STATUS)

See 2.15.1 [Machine Check Architecture]. See MSRC001\_0015[McStatusWrEn]. Table 220 describes each error type. Table 221 describes the error codes and status register settings for each error type. MSR0000\_0001 is an alias of MSR0000\_0401.

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 63   | <b>Val: error valid.</b> Read-write; set-by-hardware. Cold reset: 0. 1=This bit indicates that a valid error has been detected. This bit should be cleared to 0 by software after the register has been read.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 62   | <p><b>Overflow: error overflow.</b> Read-write; set-by-hardware. Cold reset: 0. 1=An error was detected while the valid bit (Val) was set; at least one error was not logged. Overflow is set independently of whether the existing error is overwritten.</p> <p>The following hierarchy identifies the error logging priorities.</p> <ol style="list-style-type: none"> <li>1. Uncorrectable errors</li> <li>2. Deferred errors</li> <li>3. Correctable errors</li> </ol> <p>The machine check mechanism handles the contents of MCi_STATUS during overflow as follows:</p> <ul style="list-style-type: none"> <li>• Higher priority errors overwrite lower priority errors.</li> <li>• New errors of equal or lower priority do not overwrite existing errors.</li> <li>• Uncorrectable errors which are not logged due to overflow result in setting PCC, unless the new uncorrectable error is of the same type and in the same reportable address range as the existing error.</li> </ul> |
| 61   | <b>UC: error uncorrected.</b> Read-write; Updated-by-hardware. Cold reset: 0. 1=The error was not corrected by hardware.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 60   | <b>En: error enable.</b> Read-write; Updated-by-hardware. Cold reset: 0. 1=MCA error reporting is enabled for this error, as indicated by MCi_CTL.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

**MSR0000\_0402 MC0 Machine Check Address (MC0\_ADDR)**

Read-write; Updated-by-hardware. Cold reset: 0000\_0000\_0000\_0000h. The MCi\_ADDR register contains valid data if indicated by MCi\_STATUS[AddrV]. See 2.15.1 [Machine Check Architecture]. MSR0000\_0000 is an alias of MSR0000\_0402.

| Bits | Description                          |
|------|--------------------------------------|
| 63:0 | <b>ADDR:</b> Address. See Table 222. |

| 55:52 | <b>LvtOffset: LVT offset.</b> IF ( <a href="#">MSRC001_0015</a> [McStatusWrEn]   ~Locked) THEN Read-write. ELSE Read-only. ENDIF. Reset: 0000b. BIOS: 1. Specifies the address of the LVT entry in the APIC registers as follows: LVT address = (LvtOffset shifted left 4 bits) + 500h (see <a href="#">APIC[530:500]</a> ). Only values 0 through 3 are valid; all others reserved. |
| 51    | <b>CntEn: counter enable.</b> Read-write; Updated-by-hardware. Reset: 0. 1=Count thresholding errors. See 2.15.1.7 [Error Thresholding].                                                                                                                                                                                                                                             |

|       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 50:49 | <b>IntType: interrupt type.</b> Read-write. Cold reset: 0. Specifies the type of interrupt signaled when Ovrflw is set and IntP==1.<br><div> <div>Bits</div> <div>Description</div> </div> <div> <div>00b</div> <div>No Interrupt.</div> </div> <div> <div>01b</div> <div>APIC based interrupt (see LvtOffset above) to all cores.</div> </div> <div> <div>10b</div> <div>SMI trigger event (always routed to CpuCoreNum 0, as defined in 2.4.4 [Processor Cores and Downcoring]); see 2.4.10.2.3 [SMI Sources And Delivery].</div> </div> <div> <div>11b</div> <div>Reserved</div> </div> |
| 48    | <b>Ovrflw: overflow.</b> Read-write; set-by-hardware. Cold reset: 0. Set by hardware when ErrCnt transitions from FFEh to FFFh. When this field is set, ErrCnt no longer increments. When this bit is set and the IntP field==1, the interrupt selected by the IntType field is generated.                                                                                                                                                                                                                                                                                                 |
| 47:44 | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 43:32 | <b>ErrCnt: error counter.</b> Read-write; updated-by-hardware. Cold reset: 0. This is written by software to set the starting value of the error counter. This is incremented by hardware when errors are logged. When this counter overflows, it stays at FFFh (no rollover). The threshold value, written by software, is (FFFh - the desired error count (the number of errors necessary in order for an interrupt to be taken)); the desired error count of 0 (a write value of FFFh) is not supported.                                                                                |
| 31:24 | <b>BlkPtr: Block pointer for additional MISC registers.</b> Read-only. Value: 00h. 00h=Extended MISC MSR block is not valid.                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 23:0  | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

#### MSR0000\_0404 MC1 Machine Check Control (MC1\_CTL)

[Per-compute-unit](#); Read-write.

Reset: 0000\_0000\_0000\_0000h. See 2.15.1 [Machine Check Architecture].

**Table 223: MC1 Error Descriptions**

| Error Type                   | Error                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | CTL <sup>3</sup> | CID <sup>2</sup> | EAC <sup>1</sup> |
|------------------------------|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|------------------|------------------|
| Line Fill Error              | -                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | LineFill Poison  | A                | E                |
| Instruction cache read error | IC Data Load Parity         | A parity error occurred during load of data from the instruction cache. The data is discarded from the IC and can be refetched.                                                                                                                                                                                                                                                                                                                                                                                                                                            | IDP              | A                | D                |
|                              | IC valid bit                | Parity error for IC valid bit.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | IVP              | A                | D                |
|                              | Main tag                    | A main tag parity error occurred.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | IMTP             | A                | D                |
|                              | Prediction queue            | Parity error in prediction queue.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | PQP              | A                | E                |
|                              | PFB data/address            | PFB data/address had a parity error. A PFB valid bit error, PFB multimatch error, Line Fill Error, or ReadData Error may additionally cause a PFB data/address error.                                                                                                                                                                                                                                                                                                                                                                                                      | PFBP             | A                | E                |
|                              | PFB valid bit               | PFB valid bit had a parity error. This error may cause subsequent errors related to the entry, but the effect can be contained to the running process.                                                                                                                                                                                                                                                                                                                                                                                                                     |                  | B                | E                |
|                              | PFB non-cacheable bit       | PFB non-cacheable bit had a parity error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                  | B                | E                |
|                              | PFB promotion address error | An address parity error was detected when promoting from the PFB to the IC.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                  | B                | E                |
|                              | Branch status register      | A parity error was discovered in the branch status register. This error is uncorrectable, but the effect can be contained to the running process.                                                                                                                                                                                                                                                                                                                                                                                                                          | BSRP             | A                | E                |
| Instruction cache read error | Microcode Patch Buffer      | Parity error in the microcode patch buffer. This error is uncorrectable. If a reset is not performed or the patch area is not reloaded, then it is recommended that the compute unit be removed from the running configuration by the operating system if possible. After a reset, BIST is used to determine whether there is a hard fault in the RAM. If a hard fault is not found, the error was likely a transient upset and the RAM is not broken. This error can also be caused by an error in the microcode patch region of the CC6 save area if ECC is not enabled. | DEPRP            | A                | E                |

**Table 223: MC1 Error Descriptions**

| Error Type                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Error                      | Description                                                                                                                 | CTL <sup>3</sup> | CID <sup>2</sup> | EAC <sup>1</sup> |

**MSR0000\_0406 MC1 Machine Check Address (MC1\_ADDR)**

Read-write; Updated-by-hardware. Cold reset: 0000\_0000\_0000\_0000h. The MCi\_ADDR register contains

valid data if indicated by MCi\_STATUS[AddrV]. See 2.15.1 [Machine Check Architecture].

| Bits | Description                          |
|------|--------------------------------------|
| 63:0 | <b>ADDR: Address.</b> See Table 225. |

The following table defines the address register as a function of error type.

**Table 225: MC1 Address Register**

| Error Type                   | Error Sub-Type                                                                                                                                                                                                                        | Bits         | Description                                                                                                                                                                                                                                       |              |                    |     |        |     |        |     |          |     |        |

**Table 226: MBE, SBU, and SBC Definitions**

| Term       | Definition                                                                                                                         |
|------------|------------------------------------------------------------------------------------------------------------------------------------|
| <b>MBE</b> | Multi-bit ECC error, uncorrected.                                                                                                  |
| <b>SBU</b> | Single-bit ECC error, not-corrected. There are some implementation specific conditions when a single bit error is not correctable. |
| <b>SBC</b> | Single-bit ECC error is detected and correctable.                                                                                  |

1.

EAC: The error action is taken if detected for all CU errors. D=Error action taken if detected. E=Error action taken if MCA bank enabled.See [2.15.1.3 \[Error Detection, Action, Logging, and Reporting\]](#).

2.

CID: core ID. A=Error reported to the affected core. 0=Error reported to core 0 of the compute unit; see [2.15.1.3 \[Error Detection, Action, Logging, and Reporting\]](#).

3.

See [MSR0000\\_0408](#).

4.

Error Action: [Sync flood](#)=Take sync flood if PCC=1. None=No action other than that specified by MCA.

1. LL and Way are specified in [Table 227](#).

**MSR0000\_040A MC2 Machine Check Address (MC2\_ADDR)**

Read-write; Updated-by-hardware. Cold reset: 0000\_0000\_0000\_0000h. See [2.15.1 \[Machine Check Architecture\]](#). The following table defines the address register as a function of error type.

| Bits | Description                                                                    |
|------|--------------------------------------------------------------------------------|
| 63:0 | <b>ADDR</b> . Read-write; updated-by-hardware. See <a href="#">Table 229</a> . |

**Table 229: MC2 Address Register**

| Error Type             | Error Sub-Type | Bits  | Description                 |

### MSR0000\_040C MC3 Machine Check Control (MC3\_CTL)

Reset: 0000\_0000\_0000\_0000h. Read-only.

| Bits | Description |
|------|-------------|
| 63:0 | Unused.     |

### MSR0000\_040D MC3 Machine Check Status (MC3\_STATUS)

Reset: 0. See [MSRC001\\_0015](#)[McStatusWrEn].

| Bits | Description |
|------|-------------|
| 63:0 | Reserved.   |

### MSR0000\_040E MC3 Machine Check Address (MC3\_ADDR)

Reset: 0000\_0000\_0000\_0000h. Read-only.

| Bits | Description |
|------|-------------|
| 63:0 | Reserved.   |

### MSR0000\_040F MC3 Machine Check Miscellaneous (MC3\_MISC)

Reset: 0000\_0000\_0000\_0000h. Read-only.

| Bits | Description |
|------|-------------|
| 63:0 | Reserved.   |

### MSR0000\_0410 MC4 Machine Check Control (MC4\_CTL)

Read-write; **Not-same-for-all**. Reset: 0000\_0000\_0000\_0000h.

[MSR0000\\_0410](#)[31:0] is an alias of [D18F3x40](#), which is accessible through PCI configuration space. Only one of these registers exists in multi-core devices; see [3.1.1 \[Northbridge MSRs In Multi-Core Products\]](#).

Accessibility of this register by non-NBC cores is affected by [D18F3x44](#)[NbMcaToMstCpuEn].

See [D18F3x44 \[MCA NB Configuration\]](#) for further NB MCA configuration controls. See [2.15.1 \[Machine Check Architecture\]](#) for a general description of the machine check architecture. See [MSRC001\\_0048 \[NB Machine Check Control Mask \(MC4\\_CTL\\_MASK\)\]](#) for the corresponding error mask register.

| Bits  | Description                                                                                                |

| 26    | <b>NbArrayParEn: northbridge array parity error reporting enable.</b> IF ((D18F4x118[NbPwrGate1]    D18F4x118[NbPwrGate0]    D18F4x11C[NbPwrGate2])=1) THEN BIOS: 1. ENDIF. 1=Enables reporting of parity errors in the NB arrays.                                                                                                                                                                                                                                                                                                                        |
| 25    | <b>UsPwDatErrEn: upstream data error enable.</b> Read-write. 1=Enables MCA reporting of upstream posted writes in which the EP bit is set.                                                                                                                                                                                                                                                                                                                                                                                                                |
| 24:18 | Unused.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 17    | <b>CpPktDatEn: completion packet error reporting enable.</b> Read-write. 1=Enables MCA reporting of completion packets with the EP bit set.                                                                                                                                                                                                                                                                                                                                                                                                               |
| 16    | <b>NbIntProtEn: northbridge internal bus protocol error reporting enable.</b> Read-write. 1=Enables MCA reporting of protocol errors detected on the northbridge internal bus. When possible, this enable should be cleared before initiating a warm reset to avoid logging spurious errors due to RESET_L signal skew.                                                                                                                                                                                                                                   |
| 15:13 | Unused.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 12    | <b>WDTRptEn: watchdog timer error reporting enable.</b> 1=Enables MCA reporting of watchdog timer errors. The watchdog timer checks for NB system accesses for which a response is expected but no response is received. See D18F3x44 [MCA NB Configuration] for information regarding configuration of the watchdog timer duration. This bit does not affect operation of the watchdog timer in terms of its ability to complete an access that would otherwise cause a system hang. This bit only affects whether such errors are reported through MCA. |
| 11    | <b>AtomicRMWEn: atomic read-modify-write error reporting enable.</b> 1=Enables MCA reporting of atomic read-modify-write (RMW) commands received from an IO link. Atomic RMW commands are not supported. An atomic RMW command results in a link error response being generated back to the requesting IO device. The generation of the link error response is not affected by this bit.                                                                                                                                                                  |
| 10    | Unused.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 9     | <b>TgtAbortEn: target abort error reporting enable.</b> 1=Enables MCA reporting of target aborts to a link. The NB returns an error response back to the requestor with any associated data all 1s independent of the state of this bit.                                                                                                                                                                                                                                                                                                                  |
| 8     | <b>MstrAbortEn: master abort error reporting enable.</b> 1=Enables MCA reporting of master aborts to a link. The NB returns an error response back to the requestor with any associated data all 1s independent of the state of this bit.                                                                                                                                                                                                                                                                                                                 |

**MSR0000\_0411 MC4 Machine Check Status (MC4\_STATUS)**

Not-same-for-all. Cold reset: 0000\_0000\_0000\_0000h.

MSR0000\_0411[63:32] is an alias of D18F3x4C, and MSR0000\_0411[31:0] is an alias of D18F3x48. Only one of these registers exists in multi-core devices; see 3.1.1 [Northbridge MSRs In Multi-Core Products]. Accessibility of this register by non-NBC cores is affected by D18F3x44[NbMcaToMstCpuEn]. See MSRC001\_0015[McStatusWrEn] for information on writing to this register. See 2.15.1 [Machine Check Architecture] for machine check architecture background.

Table 230 describes each error type. Table 231 and Table 232 describe the error codes and status register settings for each error type.

| Bits  | Description                                                                                                                                                                                                                                                                                          |

**Table 230: MC4 Error Descriptions**

| Error Type      | Description                                                                                                                                                                                                                                                                                                          | CTL <sup>1</sup>                   | ETG <sup>2</sup> | EAC <sup>4</sup> |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------|------------------|------------------|
| Sync Error      | Link-defined sync error packets detected on link. The NB floods its outgoing links with sync packets after detecting a sync packet on an incoming link independent of the state of the control bits.                                                                                                                 | SyncPktEn                          | L                | D                |
| Master Abort    | Master abort seen as result of link operation. Reasons for this error include requests to non-existent addresses. The NB returns an error response back to the requestor with any associated data all 1s independent of the state of the control bit.                                                                | MstrAbortEn                        | L                | D                |
| Target Abort    | Target abort seen as result of link operation. The NB returns an error response back to the requestor with any associated data all 1s independent of the state of the control bit.                                                                                                                                   | TgtAbortEn                         | L                | D                |
| RMW Error       | An atomic read-modify-write (RMW) command was received from an IO link. Atomic RMW commands are not supported. An atomic RMW command results in a link error response being generated back to the requesting IO device. The generation of the link error response is not affected by the control bit.                | AtomicRMW<br>En                    | L                | D                |
| WDT Error       | NB WDT timeout due to lack of progress. The NB WDT monitors transaction completions. A transaction that exceeds the programmed time limit reports errors via the MCA. The cause of error may be another node or device which failed to respond.                                                                      | WDTRptEn                           | L                | D                |
| DRAM ECC Error  | A DRAM ECC error detected.                                                                                                                                                                                                                                                                                           | CECCEn,<br>UECCEn                  | D                | D                |
| Link Data Error | Data error detected on link.<br>If enabled for reporting and the request is sourced from a core, then PCC is set. (If not enabled for reporting, PCC is not set. If configured to allow an error response to be returned to the core, this could allow error containment to a scope smaller than the entire system.) | McaUsPwDat<br>ErrEn,<br>CpPktDatEn | L                | D                |

1. See Table 238 [Format of MSR0000\_0412[ErrAddr[47:1]] for Watchdog Timer Errors].

2. See Table 234 [Format of MSR0000\_0412[ErrAddr[47:1]] for Protocol Errors].

3. See Table 237 [Valid Values for ArrayErrorType].

4. MS: multi-symbol. 1=Multi-symbol. 0=Not multi-symbol.

5. Core: source is core. 1=Source is core. 0=Source is not core.

6. Deferred: error is deferred. 1=Error is deferred. 0=Error is not deferred.

7. Hist: Error was detected by the hardware-managed history scheme.

### MSR0000\_0412 MC4 Machine Check Address (MC4\_ADDR)

IF (D18F3x44[NbMcaToMstCpuEn] && !NBC) THEN RAZ; Per-node; not-same-for-all. ELSE Read-write; Per-node; not-same-for-all. ENDIF. Cold reset: 0000\_0000\_0000\_0000h. See 2.15.1 [Machine Check Architecture]. MSR0000\_0412[31:0] is an alias of D18F3x50. MSR0000\_0412[63:32] is an alias of D18F3x54.

Only one of these registers exists in multi-core devices; see 3.1.1 [Northbridge MSRs In Multi-Core Products]. ErrAddr[47:1] carries supplemental information associated with a machine check error, generally the address being accessed. Accessibility of this register by non-NBC cores is affected by

[D18F3x44\[NbMcaToMstCpuEn\]](#). The format of [ErrAddr\[47:1\]](#) is a function of [MSR0000\\_0411\[ErrorCodeExt\]](#); See [ErrAddr\[47:1\]](#).

The register format depends on the type of error being logged:

- Protocol errors contain the error reason code, may contain the physical address, and are formatted according to [Table 234](#).
- NB array errors indicate the array in error, and are formatted according to [Table 236](#).
- NB Watchdog timer errors depend on the mode selected by [D18F3x180\[McaLogErrAddrWdtErr\]](#), and the format is indicated by [D18F3x4C\[AddrV\]](#). If [D18F3x4C\[AddrV\]](#) is indicated, errors are formatted according to [Table 233](#). If [D18F3x4C\[AddrV\]](#) is not indicated, errors are formatted according to [Table 238](#).
- All other NB errors which indicate [D18F3x4C\[AddrV\]](#) are formatted according to [Table 233](#).

Table 237: **Valid Values** for ArrayErrorType

| Bits    | Description                                    |
|---------|------------------------------------------------|
| 00h     | SRA: System request address.                   |
| 01h     | SRD: System request data.                      |
| 02h     | SPB: System packet buffer.                     |
| 03h     | MCD: Memory controller data.                   |
| 04h     | MPB: Memory packet buffer.                     |
| 05h     | LPB0: Link 0 packet buffer.                    |
| 08h-06h | Reserved.                                      |
| 09h     | MPBC: Memory controller command packet buffer. |
| 0Ah     | MCDBM: Memory controller byte mask.            |
| 0Bh     | MCACAM: Memory controller address array.       |
| 0Ch     | DMAP: Extended DRAM address map.               |
| 0Dh     | MMAPI: Extended MMIO address map.              |
| 0Eh     | X86MAP: Extended PCI/IO address map.           |
| 0Fh     | CFGMAP: Extended config address map.           |
| 17h-10h | Reserved.                                      |
| 18h     | SRIMCTRTE: SRI/MCT extended routing table.     |
| 1Ch-19h | Reserved                                       |
| 1Dh     | TCB: TCB array.                                |
| 1Fh-1Eh | Reserved                                       |

**Table 238:** Format of [MSR0000\\_0412](#)[ErrAddr[47:1]] for Watchdog Timer Errors

| Bits    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |      |             |         |                |         |               |     |                   |         |          |     |                    |         |          |         |                                                                                        |

| 6:1     | <b>LinkCommand.</b> When the NB WDT expires, the link command of the transaction that timed out is captured here. This field is encoded identically to the “Code” field for link transactions defined in the link specification.                                                                                                                                                                                                                                                                                                 |      |             |         |                |         |               |     |                   |         |          |     |                    |         |          |         |                                                                                        |

**MSR0000\_0413 NB Machine Check Misc 4 (DRAM Thresholding) 0 (MC4\_MISC0)**

[MSR0000\\_0413](#) is the first of the NB machine check miscellaneous registers. [MSR0000\\_0413](#) is associated with the DRAM error type. To see the remaining NB machine check miscellaneous registers, refer to [MSRC000\\_0408](#). Only one of these registers exists in multi-core devices; see [3.1.1 \[Northbridge MSRs In Multi-Core Products\]](#).

1. Causes shutdown.  
2. Causes shutdown if UC=1.  
3. STATQ sets PCC=1 if a store retired in last 3 cycles or FpTokenRet bits mismatch.

**MSR0000\_0416 MC5 Machine Check Address (MC5\_ADDR)**

Read-write; Updated-by-hardware. Cold reset: 0000\_0000\_0000\_0000h. The MCi\_ADDR register contains valid data if indicated by MCi\_STATUS[AddrV]. See 2.15.1 [Machine Check Architecture]. The register format depends on the type of error being logged.

| Bits | Description                 |
|------|-----------------------------|
| 63:0 | <b>ADDR.</b> See Table 241. |

The following tables define the address register as a function of error type.

**Table 241: MC5 Address Register**

| Error Type | Error Sub-Type       | Bits  | Description                                                                                       |
|------------|----------------------|-------|---------------------------------------------------------------------------------------------------|
| WDT        | - (ErrorCodeExt=00h) | 63:48 | Reserved                                                                                          |
|            |                      | 47:0  | <b>LogAddr[47:0].</b> Logical address of the next instruction after the last instruction retired. |

**Table 241: MC5 Address Register**

| Error Type | Error Sub-Type                                                                                                               | Bits | Description          |
|------------|------------------------------------------------------------------------------------------------------------------------------|------|----------------------|
| Internal   | AG payload array parity (ErrorCodeExt=02h), EX payload array parity (ErrorCodeExt=03h), IDRF array parity (ErrorCodeExt=04h) | 63:6 | Reserved             |
|            |                                                                                                                              | 5:0  | <b>SchedulerQID.</b> |
| Internal   | Retire dispatch queue parity (ErrorCodeExt=05h)                                                                              | 63:7 | Reserved             |
|            |                                                                                                                              | 6:0  | <b>RetirementID.</b> |
| Internal   | STATQ parity (ErrorCodeExt=0Dh)                                                                                              | 63:7 | Reserved             |
|            |                                                                                                                              | 6:0  | <b>RetirementID.</b> |
| Internal   | Mapper checkpoint array parity (ErrorCodeExt=06h)                                                                            | 63:6 | Reserved             |
|            |                                                                                                                              | 5:0  | <b>CheckpointID.</b> |

**MSR0000\_0417 MC5 Machine Check Miscellaneous (MC5\_MISC)**

Cold reset: 0000\_0000\_0000\_0000h. This register records unspecified, implementation-specific status bits when an FR machine check error is logged.

See [2.15.1.7 \[Error Thresholding\]](#).

### 3.20 MSRs - MSRC000\_0xxx

#### MSRC000\_0080 Extended Feature Enable (EFER)

SKINIT Execution: 0000\_0000\_0000\_0000h.

| Bits  | Description                                                                                                                                                                                                                                                                                                                     |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 63:16 | MBZ.                                                                                                                                                                                                                                                                                                                            |
| 15    | <b>TCE: translation cache extension enable.</b> Read-write. Reset: 0. 1=Translation cache extension is enabled.                                                                                                                                                                                                                 |
| 14    | <b>FFXSE: fast FXSAVE/FRSTOR enable.</b> Read-write. Reset: 0. 1=Enables the fast FXSAVE/FRSTOR mechanism. A 64-bit operating system may enable the fast FXSAVE/FRSTOR mechanism if ( <a href="#">CPUID Fn8000_0001_EDX</a> [FFXSR]==1)). This bit is set once by the operating system and its value is not changed afterwards. |
| 13    | <b>LMSLE: long mode segment limit enable.</b> Read-write. Reset: 0. 1=Enables the long mode segment limit check mechanism.                                                                                                                                                                                                      |
| 12    | <b>SVME: secure virtual machine (SVM) enable.</b> IF ( <a href="#">MSRC001_0114</a> [SvmeDisable]==1) THEN MBZ. ELSE Read-write. ENDIF. Reset: 0. 1=SVM features are enabled.                                                                                                                                                   |
| 11    | <b>NXE: no-execute page enable.</b> Read-write. Reset: 0. 1=The no-execute page protection feature is enabled.                                                                                                                                                                                                                  |
| 10    | <b>LMA: long mode active.</b> Read-only. Reset: 0. 1=Indicates that long mode is active.                                                                                                                                                                                                                                        |
| 9     | MBZ.                                                                                                                                                                                                                                                                                                                            |
| 8     | <b>LME: long mode enable.</b> Read-write. Reset: 0. 1=Long mode is enabled.                                                                                                                                                                                                                                                     |
| 7:1   | RAZ.                                                                                                                                                                                                                                                                                                                            |
| 0     | <b>SYSCALL: system call extension enable.</b> Read-write. Reset: 0. 1=SYSCALL and SYSRET instructions are enabled. This adds the SYSCALL and SYSRET instructions which can be used in flat addressed operating systems as low latency system calls and returns.                                                                 |

#### MSRC000\_0081 SYSCALL Target Address (STAR)

Reset: 0000\_0000\_0000\_0000h. This register holds the target address used by the SYSCALL instruction and the code and stack segment selector bases used by the SYSCALL and SYSRET instructions.

| Bits  | Description                                        |
|-------|----------------------------------------------------|
| 63:48 | <b>SysRetSel: SYSRET CS and SS.</b> Read-write.    |
| 47:32 | <b>SysCallSel: SYSCALL CS and SS.</b> Read-write.  |
| 31:0  | <b>Target: SYSCALL target address.</b> Read-write. |

#### MSRC000\_0082 Long Mode SYSCALL Target Address (STAR64)

Reset: 0000\_0000\_0000\_0000h.

| Bits | Description                                                                                                                                                                                                |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 63:0 | <b>LSTAR: long mode target address.</b> Read-write. Target address for 64-bit mode calling programs. The address stored in this register must be in canonical form (if not canonical, a #GP fault occurs). |

**MSRC000\_0083 Compatibility Mode SYSCALL Target Address (STARCOMPAT)**

Reset: 0000\_0000\_0000\_0000h.

| Bits | Description                                                                                                                                                                                               |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 63:0 | <b>CSTAR: compatibility mode target address.</b> Read-write. Target address for compatibility mode. The address stored in this register must be in canonical form (if not canonical, a #GP fault occurs). |

**MSRC000\_0084 SYSCALL Flag Mask (SYSCALL\_FLAG\_MASK)**

| Bits  | Description                                                                                                                                                                                                      |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 63:32 | RAZ.                                                                                                                                                                                                             |
| 31:0  | <b>Mask: SYSCALL flag mask.</b> Read-write. Reset: 0000_0000h. This register holds the EFLAGS mask used by the SYSCALL instruction. 1=Clear the corresponding EFLAGS bit when executing the SYSCALL instruction. |

**MSRC000\_00E7 Read-Only Max Performance Frequency Clock Count (MPerfReadOnly)**

Reset: 0000\_0000\_0000\_0000h.

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 63:0 | <b>MPerfReadOnly: read-only maximum core clocks counter.</b> IF ( <a href="#">MSRC001_0015</a> [EffFreqReadOnlyLock]) THEN Read-only; Updated-by-hardware. ELSE Read-write; Updated-by-hardware. ENDIF. Incremented by hardware at the P0 frequency while the core is in C0. This register does not increment when the core is in the stop-grant state. In combination with <a href="#">MSRC000_00E8</a> , this is used to determine the effective frequency of the core. A read of this MSR in guest mode is affected by <a href="#">MSRC000_0104</a> [Time Stamp Counter Ratio (TscRateMsr)]. This field uses software P-state numbering. See <a href="#">MSRC001_0015</a> [EffFreqCntMwait], <a href="#">2.5.3.3</a> [Effective Frequency], and <a href="#">2.5.3.1.1.1</a> [Software P-state Numbering]. This register is not affected by writes to <a href="#">MSR0000_00E7</a> . |

**MSRC000\_00E8 Read-Only Actual Performance Frequency Clock Count (APerfReadOnly)**

Reset: 0000\_0000\_0000\_0000h.

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 63:0 | <b>APerfReadOnly: read-only actual core clocks counter.</b> IF ( <a href="#">MSRC001_0015</a> [EffFreqReadOnlyLock]) THEN Read-only; Updated-by-hardware. ELSE Read-write; Updated-by-hardware. ENDIF. This register increments in proportion to the actual number of core clocks cycles while the core is in C0. The register does not increment when the core is in the stop-grant state. See <a href="#">MSRC000_00E7</a> . This register is not affected by writes to <a href="#">MSR0000_00E8</a> . |

**MSRC000\_0100 FS Base (FS\_BASE)**

Reset: 0000\_0000\_0000\_0000h.

| Bits | Description                                                                                                                                                                                                                                             |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 63:0 | <b>FSBase: expanded FS segment base.</b> Read-write; not-same-for-all. This register provides access to the expanded 64-bit FS segment base. The address stored in this register must be in canonical form (if not canonical, a #GP fault fill occurs). |

#### MSRC000\_0101 GS Base (GS\_BASE)

Reset: 0000\_0000\_0000\_0000h.

| Bits | Description                                                                                                                                                                                                                                             |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 63:0 | <b>GSBase: expanded GS segment base.</b> Read-write; not-same-for-all. This register provides access to the expanded 64-bit GS segment base. The address stored in this register must be in canonical form (if not canonical, a #GP fault fill occurs). |

#### MSRC000\_0102 Kernel GS Base (KernelGSbase)

Reset: 0000\_0000\_0000\_0000h.

| Bits | Description                                                                                                                                                                                                                                                                                              |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 63:0 | <b>KernelGSBase: kernel data structure pointer.</b> Read-write. This register holds the kernel data structure pointer which can be swapped with the GS_BASE register using the SwapGS instruction. The address stored in this register must be in canonical form (if not canonical, a #GP fault occurs). |

#### MSRC000\_0103 Auxiliary Time Stamp Counter (TSC\_AUX)

Reset: 0000\_0000\_0000\_0000h.

| Bits  | Description                                                                                                                                                                                                                   |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 63:32 | Reserved.                                                                                                                                                                                                                     |
| 31:0  | <b>TscAux: auxiliary time stamp counter data.</b> Read-write. It is expected that this is initialized by privileged software to a meaningful value, such as a processor ID. This value is returned in the RDTSCP instruction. |

#### MSRC000\_0104 Time Stamp Counter Ratio (TscRateMsr)

[MSRC000\\_0104 \[Time Stamp Counter Ratio \(TscRateMsr\)\]](#) allows the hypervisor to control the guest's view of the Time Stamp Counter. It provides a multiplier that scales the value returned when [MSR0000\\_0010\[TSC\]](#), [MSR0000\\_00E7\[MPERF\]](#), and [MSRC000\\_00E7\[MPerfReadOnly\]](#) are read by a guest running under virtualization. This allows the hypervisor to provide a consistent TSC, MPERF, and MPerfReadOnly rate for a guest process when moving that process between cores that have a differing P0 rate. The TSC Ratio MSR does not affect the value read from the TSC, MPERF, and MPerfReadOnly MSRs when read when in host mode or when virtualization is not being used or when accessed by code executed in system management mode (SMM) unless the SMM code is executed within a guest container. The TSC Ratio value does not affect the rate of the underlying TSC, MPERF, and MPerfReadOnly counters, or the value that gets written to the TSC, MPERF, and MPerfReadOnly MSRs counters on a write by either the host or the guest. The TSC Ratio MSR contains a fixed-point number in 8.32 format, which is 8 bits of integer and 32 bits of fraction. This number is the ratio of the desired P0 frequency to the P0 frequency of the core. The reset value of the TSC Ratio MSR is 1.0, which results in a guest frequency matches the core P0 frequency.

| Bits  | Description                                                                                                                                       |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| 63:40 | MBZ.                                                                                                                                              |
| 39:32 | <b>TscRateMsrInt: time stamp counter rate integer.</b> Read-write. Reset: 01h. Specifies the integer part of the MSR TSC ratio value.             |
| 31:0  | <b>TscRateMsrFrac: time stamp counter rate fraction.</b> Read-write. Reset: 0000_0000h. Specifies the fractional part of the MSR TSC ratio value. |

### MSRC000\_0105 Lightweight Profile Configuration (LWP\_CFG)

| Bits  | Description                                                                                                                                                                                                                                               |

### MSRC000\_0106 Lightweight Profile Control Block Address (LWP\_CBADDR)

Access to the internal copy of the LWPCB logical line/64 B address. A read returns the current LWPCB address without performing any of the operations described for the SLWPCB instruction. A write to this regis-

ter with a non-zero value will cause a #GP fault. Use LLWPCB or XRSTOR to load an LWPCB address. Writing a zero to LWP\_CBADDR will immediately disable LWP, discarding any internal state. For instance, an operating system can write a zero to stop LWP when it terminates a thread. All references to the LWPCB implicitly use the DS segment register. Must be 64 B aligned.

| Bits | Description                                                                                                                |
|------|----------------------------------------------------------------------------------------------------------------------------|
| 63:6 | <b>LwpCbAddr[63:6]: control block logical address.</b> Read-write. Reset: 0. LwpCbAddr[63:0] = {LwpCbAddr[63:6], 000000b}. |
| 5:0  | RAZ.                                                                                                                       |

#### **MSRC000\_0408 NB Machine Check Misc 4 (Link Thresholding) 1 (MC4\_MISC1)**

Per-node. [MSRC000\\_0408](#) is associated with the link error type. See [2.15.1.7 \[Error Thresholding\]](#). Accessibility of this register by non-NBC cores is affected by [D18F3x44\[NbMcaToMstCpuEn\]](#).

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| 17    | <b>Wrap32Dis: 32-bit address wrap disable.</b> Read-write. Reset: 0. 1=Disable 32-bit address wrapping. Software can use Wrap32Dis to access physical memory above 4 Gbytes without switching into 64-bit mode. To do so, software should write a greater-than 4 Gbyte address to <a href="#">MSRC000_0100 [FS Base (FS_BASE)]</a> and <a href="#">MSRC000_0101 [GS Base (GS_BASE)]</a> . Then it would address $\pm 2$ Gbytes from one of those bases using normal memory reference instructions with a FS or GS override prefix. However, the INVLPG, FST, and SSE store instructions generate 32-bit addresses in legacy mode, regardless of the state of Wrap32Dis.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| 0   | <b>SmmLock: SMM code lock.</b> Read; write-1-only. Reset: 0. SBIOS: 1. 1=SMM code in the ASeg and TSeg range and the SMM registers are read-only and SMI interrupts are not intercepted in SVM. See <a href="#">2.4.9.2.9 [Locking SMM]</a> .                                                                                                                                                                                                                                                                                              |

### MSRC001\_00[18,16] IO Range Base (IORR\_BASE[1:0])

**Per-compute-unit.** Reset: X. MSRC001\_0016 and MSRC001\_0017 combine to specify the first IORR range and MSRC001\_0018 and MSRC001\_0019 combine to specify the second IORR range. A core access, with address CPUAddr, is determined to be within IORR address range if the following equation is true:

$\text{CPUAddr}[47:12] \& \text{PhyMask}[47:12] == \text{PhyBase}[47:12] \& \text{PhyMask}[47:12]$ .

BIOS can use the IORRs to create an IO hole within a range of addresses that would normally be mapped to DRAM. It can also use the IORRs to re-assert a DRAM destination for a range of addresses that fall within a bigger IO hole that overlays DRAM. See [2.4.6.1.2 \[Determining The Access Destination for Core Accesses\]](#).

| 31    | <b>DisCohLdtCfg: disable coherent link configuration accesses</b> . Reset: 0. 1=Disables automatic routing of PCI configuration accesses to the processor configuration registers; PCI configuration space accesses which fall within the hard-coded range reserved for processor configuration-space registers are instead routed to the IO link specified by <a href="#">D18F1x[1DC:1D0,EC:E0]</a> [ <a href="#">Configuration Map</a> ]. This can be used to effectively hide the configuration registers from software. It can also be used to provide a means for an external chip to route processor configuration accesses according to a scheme other than the hard-coded version. When used, this bit needs to be set on all processors in a system. PCI configuration accesses should not be generated if this bit is not set on all processors. |
| 30:28 | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

### MSRC001\_00[35:30] Processor Name String

[Per-compute-unit](#); [SharedNC](#).

Reset: 0000\_0000\_0000\_0000h. BIOS: [Table 247](#). These registers holds the CPUID name string in ASCII. The state of these registers are returned by CPUID instructions, [CPUID Fn8000\\_000\[4:2\]\\_E\[D,C,B,A\]X](#). BIOS should set these registers to the product name for the processor as provided by AMD. Each register contains a block of 8 ASCII characters; the least byte corresponds to the first ASCII character of the block; the most-significant byte corresponds to the last character of the block. MSRC001\_0030 contains the first block of the name string; MSRC001\_0035 contains the last block of the name string.

Table 246: [Register Mapping](#) for [MSRC001\\_00\[35:30\]](#)

| Register     | Function         |
|--------------|------------------|
| MSRC001_0030 | Characters 7-0   |
| MSRC001_0031 | Characters 15-8  |
| MSRC001_0032 | Characters 23-16 |
| MSRC001_0033 | Characters 31-24 |
| MSRC001_0034 | Characters 39-32 |
| MSRC001_0035 | Characters 47-40 |

See [D18F5x194](#) for the access method to [D18F5x198\\_x\[B:0\]](#).

**Table 247: BIOS Recommendations for MSRC001\_00[35:30]**

| Register     | BIOS                         |
|--------------|------------------------------|
| MSRC001_0030 | {D18F5x198_x1, D18F5x198_x0} |
| MSRC001_0031 | {D18F5x198_x3, D18F5x198_x2} |

### **MSRC001\_00[53:50] IO Trap (SMI\_ON\_IO\_TRAP\_[3:0])**

Per-compute-unit; SharedNC.

Reset: 0000\_0000\_0000\_0000h.

[MSRC001\\_00\[53:50\]](#) and [MSRC001\\_0054](#) provide a mechanism for executing the SMI handler if a an access to one of the specified addresses is detected. Access address and access type checking is performed before IO instruction execution. If the access address and access type match one of the specified IO address and access types, then: (1) the IO instruction is not executed; (2) any breakpoint, other than the single-step breakpoint, set on the IO instruction is not taken (the single-step breakpoint is taken after resuming from SMM); and (3) the SMI-trigger IO cycle specified by [MSRC001\\_0056](#). The status is stored in [SMMFEC4\[IoTrapSts\]](#).

IO-space configuration accesses are special IO accesses. An IO access is defined as an IO-space configuration access when IO instruction address bits[31:0] are CFCh, CFDh, CFEh, or CFFh when IO-space configuration is enabled ([IOCF8\[ConfigEn\]](#)). The access address for a configuration space access is the current value of [IOCF8\[BusNo, Device, Function, RegNo\]](#). The access address for an IO access that is not a configuration access is equivalent to the IO instruction address, bits[31:0].

The access address is compared with SmiAddr, and the instruction access type is compared with the enabled access types defined by ConfigSMI, SmiOnRdEn, and SmiOnWrEn. Access address bits[23:0] can be masked with SmiMask.

IO and configuration space trapping to SMI applies only to single IO instructions; it does not apply to string and REP IO instructions.

The conditional GP fault described by [MSRC001\\_0015\[IoCfgGpFault\]](#) takes priority over this trap.

**MSRC001\_0055 Interrupt Pending**

[Per-compute-unit](#); [SharedNC](#). This register is used to specify messages that the processor generates under certain conditions, that target the IO hub. One purpose is to ensure that the IO hub can wake the processor out of the stop-grant state when there is a pending interrupt. Otherwise, it is possible for the processor to remain in the stop-grant state while an interrupt is pending in the processor. This is accomplished by sending a message to the IO hub to indicate that the interrupt is pending. There are two message types: a programmable IO-space message and the link INT\_PENDING message defined by the link specification.

If the IO hub does not support the INT\_PENDING message, the IO space message should be selected by IntPndMsg. When this is enabled, the check for a pending interrupt is performed at the end of each IO instruction. If there is a pending interrupt and STPCLK is asserted, the processor executes a byte-size IO access as specified by IORd, IOMsgAddr, and IOMsgData.

If the IO hub supports the INT\_PENDING message, it should be selected by IntPndMsg. The check for a pending interrupt is performed while in the stop-grant state or when entering the stop-grant state. If there is a pending interrupt, the processor broadcasts the INT\_PENDING message. An INT\_PENDING message may not be generated for arbitrated interrupts in multi-node systems.

### MSRC001\_0056 SMI Trigger IO Cycle

**Not-same-for-all.** Reset: 0000\_0000\_0000\_0000h. See [2.4.9.2.3 \[SMI Sources And Delivery\]](#). This register specifies an IO cycle that may be generated when a local SMI trigger event occurs. If IoCycleEn is set and there is a local SMI trigger event, then the IO cycle generated is a byte read or write, based on IoRd, to address IoPortAddress. If the cycle is a write, then IoData contains the data written. If the cycle is a read, the value read is discarded. If IoCycleEn is clear and a local SMI trigger event occurs, then undefined behavior results.

| Bits  | Description                                                                                           |

### MSRC001\_0060 BIST Results

Read; GP-write. Reset: 0000\_0000\_xxxx\_xxxxh. This register provides BIST results after each reset. The results provided here are identical to the values provided in EAX. If (MSRC001\_0060[29:0]=0000\_0000h) then no BIST failures were detected.

| 2:0  | <b>CurPstate: current P-state.</b> Cold reset: Varies by product. This field provides the frequency component of the current non-boosted P-state of the core (regardless of the source of the P-state change, including <a href="#">MSRC001_0062[PstateCmd]</a> ; see <a href="#">2.5.3.1.5 [Core P-state Transition Behavior]</a> for information on how these interact). 0=P0, 1=P1, etc. The value of this field is updated when the COF transitions to a new value associated with a P-state. This field uses software P-state numbering. See <a href="#">2.5.3 [CPU Power Management]</a> and <a href="#">2.5.3.1.1.1 [Software P-state Numbering]</a> . |

**MSRC001\_00[6B:64] P-state [7:0]**

[Per-node](#). Cold reset: Varies by product. Each of these registers specify the frequency and voltage associated with each of the core P-states.

Table 249: [Register Mapping](#) for [MSRC001\\_00\[6B:64\]](#)

| Register     | Function  |
|--------------|-----------|
| MSRC001_0064 | P-state 0 |
| MSRC001_0065 | P-state 1 |
| MSRC001_0066 | P-state 2 |
| MSRC001_0067 | P-state 3 |
| MSRC001_0068 | P-state 4 |
| MSRC001_0069 | P-state 5 |
| MSRC001_006A | P-state 6 |
| MSRC001_006B | P-state 7 |

The CpuVid field in these registers is required to be programmed to the same value in all cores of a processor, but are allowed to be different between processors in a multi-processor system. All other fields in these registers are required to be programmed to the same value in each core of the coherent fabric. See [2.5.3 \[CPU Power Management\]](#).

When [D18F4x15C\[BoostLock\]=1](#), [MSRC001\\_00\[6B:64\]\[CpuVid, CpuDid, CpuFid\]](#) have special write

requirements associated with them.

| 5:0   | <b>CpuFid[5:0]: core frequency ID.</b> Read-write. Except as required by <a href="#">2.5.3.1.7 [Processor-Systemboard Power Delivery Compatibility Check]</a> , software should not modify this field. Specifies the core frequency multiplier. The core COF is a function of CpuFid and CpuDid, and defined by <a href="#">CoreCOF</a> .                                                                                                                                                                                                                                   |      |             |    |             |    |             |    |             |    |             |    |              |       |          |

### MSRC001\_0070 COFVID Control

Cold reset: Product-specific. There is one register implemented for each core. This register includes several fields that are identical to [MSRC001\\_00\[6B:64\]](#). It is controlled by hardware for P-state transitions. It may also be used by software to directly control the current COF or VID.

.Accesses to this register that result in invalid COFs or VIDs are ignored. See [2.5.3 \[CPU Power Management\]](#).

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                        |

| 15:0  | <b>CstateAddr: C-state address.</b> Read-write. Specifies the IO addresses trapped by the core for C-state entry requests. A value of 0 in this field specifies that the core does not trap any IO addresses for C-state entry. Writing values greater than FFF8h into this field result in undefined behavior. All other values cause the core to trap IO addresses CstateAddr through CstateAddr+7. See <a href="#">2.5.3.2.2 [C-state Request Interface]</a> , <a href="#">D18F4x11[C:8]</a> , and <a href="#">D18F4x11C</a> . |

### MSRC001\_0074 CPU Watchdog Timer (CpuWdtCfg)

Read-write; [Same-for-all](#). Reset: 0000\_0000\_0000\_0000h.

The CPU watchdog timer (WDT) is implemented as a counter that counts out the time periods specified. The counter starts counting when CpuWdtEn is set. The counter does not count during halt or stop-grant. It restarts the count each time an operation of an instruction completes. If no operation completes by the specified time period, then a machine check error may be recorded if enabled (see [MSR0000\\_0414](#) through [MSR0000\\_0417](#)). If a watchdog timer error overflow occurs ([MSR0000\\_0415\[Overflow\]](#)), a sync flood can be generated if enabled in [D18F3x180\[SyncFloodOnCpuLeakErr\]](#).

The CPU watchdog timer must be set higher than the NB watchdog timer ([D18F3x44 \[MCA NB Configuration\]](#)) in order to allow remote requests to complete. The CPU watchdog timer must be set the same for all CPUs in a system.

| 6:3 | <b>CpuWdtCountSel: CPU watchdog timer count select.</b> CpuWdtCountSel and CpuWdtTimeBase together specify the time period required for the WDT to expire. The time period is ((the multiplier specified by CpuWdtCountSel) * (the time base specified by CpuWdtTimeBase)). The actual timeout period may be anywhere from zero to one increments less than the values specified, due to non-deterministic behavior. |                    |             |                   |

#### MSRC001\_0111 SMM Base Address (SMM\_BASE)

Reset: 0000\_0000\_0003\_0000h. This holds the base of the SMM memory region. The value of this register is stored in the save state on entry into SMM (see 2.4.9.2.5 [SMM Save State]) and it is restored on returning from SMM. The 16-bit CS (code segment) selector is loaded with SmmBase[19:4] on entering SMM.

SmmBase[3:0] is required to be 0. The SMM base address can be changed in two ways:

- The SMM base address, at offset FF00h in the SMM state save area, may be changed by the SMI handler. The RSM instruction updates SmmBase with the new value.
- Normal WRMSR access to this register.

| Bits  | Description                                                                                                                        |

#### MSRC001\_0112 SMM TSeg Base Address (SMMAddr)

Reset: 0000\_0000\_0000\_0000h.

See 2.4.9.2 [System Management Mode (SMM)] and 2.4.6.1 [Memory Access to the Physical Address Space]. See MSRC001\_0113 for more information about the ASeg and TSeg address ranges.

Each CPU access, directed at CPUAddr, is determined to be in the TSeg range if the following is true:

$\text{CPUAddr}[47:17] \& \text{TSegMask}[47:17] == \text{TSegBase}[47:17] \& \text{TSegMask}[47:17]$ .

For example, if TSeg spans 256 KB and starts at the 1 MB address. The MSRC001\_0112[TSegBase] would be set to 0010\_0000h and the MSRC001\_0113[TSegMask] to FFFC\_0000h (with zeros filling in for bits[16:0]).

This results in a TSeg range from 0010\_0000 to 0013\_FFFFh.

### MSRC001\_0113 SMM TSeg Mask (SMMMask)

Reset: 0000\_0000\_0000\_0000h. See [2.4.9.2 \[System Management Mode \(SMM\)\]](#).

The ASeg address range is located at a fixed address from A0000h–BFFFFh. The TSeg range is located at a variable base (specified by [MSRC001\\_0112](#)[TSegBase]) with a variable size (specified by [MSRC001\\_0113](#)[TSegMask]). These ranges provide a safe location for SMM code and data that is not readily accessible by non-SMM applications. The SMI handler can be located in one of these two ranges, or it can be located outside these ranges. These ranges must never overlap each other.

This register specifies how accesses to the ASeg and TSeg address ranges are controlled as follows:

- If [A,T]Valid=1, then:
  - If in SMM, then:
    - If [A, T]Close=0, then the accesses are directed to DRAM with memory type as specified in [A, T]MTypeDram.
    - If [A, T]Close=1, then instruction accesses are directed to DRAM with memory type as specified in [A, T]MTypeDram and data accesses are directed at MMIO space and with attributes based on [A, T]MTypeIoWc.
  - If not in SMM, then the accesses are directed at MMIO space with attributes based on [A,T]MTypeIoWc.
- See [2.4.6.1.1 \[Determining Memory Type\]](#).

| 63:32 | Reserved.                                                                                                                            |
| 31:1  | MBZ.                                                                                                                                 |
| 0     | <b>IGNNE: current IGNNE state.</b> Read-write. Reset: 0. This bit controls the current state of the processor internal IGNNE signal. |

**MSRC001\_0116 SMM Control (SMM\_CTL)**

IF (MSRC001\_0015[SmmLock]) THEN GP-read-write. ELSE GP-read; write-only. ENDIF.

The bits in this register are processed in the order of: SmmEnter, SmiCycle, SmmDismiss, RsmCycle and SmmExit. However, only the following combination of bits may be set in a single write (all other combinations result in undefined behavior):

- SmmEnter and SmiCycle.
- SmmEnter and SmmDismiss.
- SmmEnter, SmiCycle and SmmDismiss.
- SmmExit and RsmCycle.

Software is responsible for ensuring that SmmEnter and SmmExit operations are properly matched and are not nested.

| 18      | <b>Edge: edge detect.</b> Read-write. 0=Level detect. 1=Edge detect. The edge count mode increments the counter when a transition happens on the monitored event. If the event selected is changed without disabling the counter, an extra edge is falsely detected when the first event is a static 0 and the second event is a static one. To avoid this false edge detection, disable the counter when changing the event and then enable the counter with a second MSR write.                                                                                                                                                                                                                                                                                        |      |             |     |                                                                                                                                                      |         |                                                                                                                                                                                                                                                                                                                                     |         |                                                             |     |                                                                           |

|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15:8 | <b>UnitMask: event qualification.</b> Read-write. Each UnitMask bit further specifies or qualifies the event specified by EventSelect. All events selected by UnitMask are simultaneously monitored. Unless otherwise stated, the UnitMask values shown may be combined (logically ORed) to select any desired combination of the sub-events for a given event. In some cases, certain combinations can result in misleading counts, or the UnitMask value is an ordinal rather than a bit mask. These situations are described where applicable, or should be obvious from the event descriptions. For events where no UnitMask table is shown, the UnitMask is <b>Unused</b> . |
| 7:0  | <b>EventSelect[7:0]: event select.</b> Read-write. EventSelect[11:0] = {EventSelect[11:8], EventSelect[7:0]}. EventSelect specifies the event or event duration in a processor unit to be counted by the corresponding PERF_CTR[5:0] register. The events are specified in <a href="#">3.23 [Core Performance Counter Events]</a> . Some events are reserved; when a reserved event is selected, the results are undefined.                                                                                                                                                                                                                                                      |

### MSRC001\_020[B,9,7,5,3,1] Performance Event Counter (PERF\_CTR[5:0])

See [MSRC001\\_020\[A,8,6,4,2,0\] \[Performance Event Select \(PERF\\_CTL\[5:0\]\)\]](#). MSRC001\_00[07:04] is an alias of MSRC001\_020[7,5,3,1].

Table 252: [Register Mapping](#) for MSRC001\_020[B,9,7,5,3,1]

| Register     | Function  |

| 15:8  | <b>UnitMask: event qualification.</b> Read-write. Reset: 0. Each UnitMask bit further specifies or qualifies the event specified by EventSelect. All events selected by UnitMask are simultaneously monitored. Unless otherwise stated, the UnitMask values shown may be combined (logically ORed) to select any desired combination of the sub-events for a given event. In some cases, certain combinations can result in misleading counts, or the UnitMask value is an ordinal rather than a bit mask. These situations are described where applicable, or should be obvious from the event descriptions. For events where no UnitMask table is shown, the UnitMask is <a href="#">Unused</a> . |
| 7:0   | <b>EventSelect[7:0]: event select.</b> Read-write. Reset: 0. This field, along with EventSelect[11:8] above, combine to form the 12-bit event select field, EventSelect[11:0]. EventSelect specifies the event or event duration in a processor unit to be counted by the corresponding NB_PERF_CTR[3:0] register. The events are specified in <a href="#">3.24 [NB Performance Counter Events]</a> . Some events are reserved; when a reserved event is selected, the results are undefined.                                                                                                                                                                                                       |

| 31:0  | <b>AddrMask: mask for DR linear address data breakpoint.</b> Read-write. This field qualifies the DR linear address data breakpoint, allowing the DR[3:1] data breakpoint on a range of addresses in memory. The mask bits are active high; 0=Include bit into address compare; 1=Exclude bit into address compare. AddrMask is always used, and it can be used in conjunction with any debug function that uses DR[3:1]. The legacy DR breakpoint function is provided by AddrMask[31:0]==0000_0000h). |

### MSRC001\_1020 Load-Store Configuration (LS\_CFG)

| 31:0  | <b>AddrMaskDR0: mask for DR0 linear address data breakpoint.</b> Read-write. This field qualifies the DR0 linear address data breakpoint, allowing the DR0 data breakpoint on a range of addresses in memory. The mask bits are active high; 0=Include bit into address compare; 1=Exclude bit into address compare. AddrMaskDR0 is always used, and it can be used in conjunction with any debug function that uses DR0. AddrMaskDR0[31:12] is only valid for data breakpoints. The legacy DR0 breakpoint function is provided by AddrMaskDR0[31:0]==0000_0000h). |

| 9     | <b>L2UpsizeCSWT[0]: L2 upsize context switch warmup threshold [0]</b> . Read-write. Reset: 0. BIOS: 0b. L2UpsizeCSWT[4:0] = {L2UpsizeCSWT[4:1], L2UpsizeCSWT[0]}.<br>The L2UpsizeCSWT defines the context switch warmup threshold for L2 cache upsize. When non-zero, both the internal eviction count and the internal committed uop count are cleared when either a context switch occurs (indicated by MOV CR3) or the committed uop count exceeds the L2UpsizeCSWT[4:0]*8K following a context switch. This defines a period where many rapid evictions can occur without causing an L2 cache upsize following a context switch.                                                                                                                                                                                                             |      |             |    |           |    |          |    |           |    |           |       |           |

| 4:0   | <b>L2UpsizeERT: L2 upsize evict rate threshold</b> . Read-write. Reset: 0. BIOS: 01101b.<br>The L2UpsizeERT defines the eviction rate threshold that can cause an L2 cache upsize after a CC6 exit. When L2UpsizeERT is zero, the L2 cache upsize mechanism is disabled. When L2UpsizeERT is non-zero, L2 cache upsizes can be triggered after the internal committed uop counter interval expires (defined by L2UpsizeCUCT) if the internal eviction counter equals or exceeds the L2UpsizeERT[4:0]*64. Ratios of the L2UpsizeERT and L2UpsizeCUCT support a range of 0.00024 through 0.25 evictions per committed uop for L2 cache upsize tuning.                                                                                                                                                                                              |      |             |    |           |    |          |    |           |    |           |       |           |

### MSRC001\_102B Combined Unit Configuration 3 (CU\_CFG3)

### MSRC001\_102F Prefetch Throttling Configuration (CU\_PFTCFG)

Read-write; **Per-compute-unit**. Reset: 0000\_0000\_0000\_0000h.

The prefetch throttle mechanism, described as follows, is enabled when (PrefetchThrottlingEn==1), otherwise all L2 prefetches will be sent to the NB.

A tracking structure is defined that holds 4 NB prefetches. Each of the 4 prefetches in this structure stores a hashed physical address (PAHash[13:0]), computed as (PA[47:34] ^ PA[33:20] ^ PA[19:6]). Every Nth prefetch sent to the NB, where N is specified by CaptureThreshold, will replace the oldest entry in the tracking structure. Each entry in the tracking structure implements a DemandHit indication, that is initialized as 0 when inserted and set to 1 if a demand L2 hit also hits on that entry, where a hit is defined as when the L2 hit PAHash matches the entry PAHash.

Two counters are defined, a current accuracy count (AccCntCurrent[5:0]), warm reset to 0, and a previous accuracy count (AccCntPrevious[5:0]), warm reset to 3Fh. AccCntCurrent is incremented if the entry that is replaced by a tracking structure insertion is DemandHit==1. After TrackThreshold insertions to the tracking structure, AccCntCurrent is written to AccCntPrevious and AccCntCurrent=0. All throttling decisions are based on the value of AccCntPrevious.

DCT channel utilization also factors into the decision to throttle prefetches. DCT utilization is indicated by a code called DramBwLevel, ranging from 0 (low utilization) to 2 (high utilization). If DRAM prefetch watermark 2 has been reached then DramBwLevel=2, else if DRAM prefetch watermark 1 has been reached then DramBwLevel=1, else DramBwLevel=0. See D18F2x1B4[DcqBwThrotWm2, DcqBwThrotWm1]. Throttling occurs according to ThrottleLevel as a function of DramBwLevel:

- If ((DramBwLevel==0) && (AccCntPrevious < AccThresh0)) then throttle.
- If ((DramBwLevel==1) && (AccCntPrevious < AccThresh1)) then throttle.
- If ((DramBwLevel==2) && (AccCntPrevious < AccThresh2)) then throttle.

| Bits    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |      |             |     |          |     |                                                  |         |                                                                                  |     |                                                      |

### MSRC001\_1030 IBS Fetch Control (IbsFetchCtl)

Reset: 0000\_0000\_0000\_0000h. See 2.6.2 [Instruction Based Sampling (IBS)].

The IBS fetch sampling engine is described as follows:

- The periodic fetch counter is an internal 20-bit counter:
  - The periodic fetch counter [19:4] is set to IbsFetchCnt[19:4] and the periodic fetch counter [3:0] is set according to IbsRandEn when IbsFetchEn is changed from 0 to 1.
  - It increments for every fetch cycle that completes when IbsFetchEn=1 and IbsFetchVal=0.
    - The periodic fetch counter is undefined when IbsFetchEn=0 or IbsFetchVal=1.
  - When IbsFetchCnt[19:4] is read it returns the current value of the periodic fetch counter [19:4].
- When the periodic fetch counter reaches {IbsFetchMaxCnt[19:4],0h} and the selected instruction fetch completes or is aborted:
  - IbsFetchVal is set to 1.
    - Drivers can't assume that IbsFetchCnt[19:4] is 0 when IbsFetchVal==1.
  - The status of the operation is written to the IBS fetch registers (this register, [MSRC001\\_1031](#) and [MSRC001\\_1032](#)).
  - An interrupt is generated as specified by [MSRC001\\_103A](#). The interrupt service routine associated with this interrupt is responsible for saving the performance information stored in IBS execution registers.

| Bits  | Description                                                                                                                                                                                                                                                                 |

| 50    | <b>IbsFetchComp: instruction fetch complete.</b><br>Read-only; set-by-hardware. 1=The instruction fetch completed and the data is available for use by the instruction decoder.                                                                                                                                                                                                                                                                  |      |             |     |      |     |      |     |      |     |          |
| 49    | <b>IbsFetchVal: instruction fetch valid.</b> Read-only; set-by-hardware. 1=New instruction fetch data available. When this bit is set, the fetch counter stops counting and an interrupt is generated as specified by <a href="#">MSRC001_103A</a> . This bit must be cleared for the fetch counter to start counting. When clearing this bit, software can write 0000h to IbsFetchCnt[19:4] to start the fetch counter at IbsFetchMaxCnt[19:4]. |      |             |     |      |     |      |     |      |     |          |
| 48    | <b>IbsFetchEn: instruction fetch enable.</b> Read-write. 1=Instruction fetch sampling is enabled.                                                                                                                                                                                                                                                                                                                                                |      |             |     |      |     |      |     |      |     |          |
| 47:32 | <b>IbsFetchLat: instruction fetch latency.</b> Read-only; set-by-hardware. Indicates the number of clock cycles from when the instruction fetch was initiated to when the data was delivered to the core. If the instruction fetch is abandoned before the fetch completes, this field returns the number of clock cycles from when the instruction fetch was initiated to when the fetch was abandoned.                                         |      |             |     |      |     |      |     |      |     |          |
| 31:16 | <b>IbsFetchCnt[19:4].</b> Read-write; updated-by-hardware. Provides read/write access to bits[19:4] of the periodic fetch counter. Programming this field to a value greater than or equal to IbsFetchMaxCnt[19:4] results in undefined behavior.                                                                                                                                                                                                |      |             |     |      |     |      |     |      |     |          |
| 15:0  | <b>IbsFetchMaxCnt[19:4].</b> Read-write. Specifies bits[19:4] of the maximum count value of the periodic fetch counter. Programming this field to 0000h and setting IbsFetchEn results in undefined behavior. Bits[3:0] of the maximum count are always 0000b.                                                                                                                                                                                   |      |             |     |      |     |      |     |      |     |          |

#### MSRC001\_1031 IBS Fetch Linear Address (IbsFetchLinAd)

Reset: 0000\_0000\_0000\_0000h.

| Bits | Description                                                                                                                                                              |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 63:0 | <b>IbsFetchLinAd: instruction fetch linear address.</b> Read-write; updated-by-hardware. Provides the linear address in canonical form for the tagged instruction fetch. |

#### MSRC001\_1032 IBS Fetch Physical Address (IbsFetchPhysAd)

Reset: 0000\_0000\_0000\_0000h.

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                  |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 63:0 | <b>IbsFetchPhysAd: instruction fetch physical address.</b> Read-write; updated-by-hardware. Provides the physical address for the tagged instruction fetch. The lower 12 bits are not modified by address translation, so they are always the same as the linear address. This field contains valid data only if <a href="#">MSRC001_1030</a> [IbsPhyAddrValid] is asserted. |

### MSRC001\_1033 IBS Execution Control (IbsOpCtl)

Reset: 0000\_0000\_0000\_0000h. See [2.6.2 \[Instruction Based Sampling \(IBS\)\]](#).

The IBS execution sampling engine is described as follows for IbsOpCntCtl==1. If IbsOpCntCtl==1n then references to “periodic op counter” mean “periodic cycle counter”.

- The periodic op counter is an internal 27-bit counter:
  - It is set to IbsOpCurCnt[26:0] when IbsOpEn is changed from 0 to 1.
  - It increments every dispatched op when IbsOpEn=1 and IbsOpVal=0.
    - The periodic op counter is undefined when IbsOpEn=0 or IbsOpVal=1.
  - When IbsOpCurCnt[26:0] is read then it returns the current value of the periodic micro-op counter [26:0].
- When the periodic micro-op counter reaches IbsOpMaxCnt:
  - The next dispatched micro-op is tagged if IbsOpCntCtl==1. A valid op in the next dispatched line is tagged if IbsOpCntCtl==0. See IbsOpCntCtl.
  - The periodic micro-op counter [26:7]=0; [6:0] is randomized by hardware.
- The periodic micro-op counter is not modified when a tagged micro-op is flushed.
- When a tagged micro-op is retired:
  - IbsOpVal is set to 1.
    - Drivers can't assume that IbsOpCurCnt is 0 when IbsOpVal==1.
  - The status of the operation is written to the IBS execution registers (this register, [MSRC001\\_1034](#), [MSRC001\\_1035](#), [MSRC001\\_1036](#), [MSRC001\\_1037](#), [MSRC001\\_1038](#) and [MSRC001\\_1039](#)).
  - An interrupt is generated as specified by [MSRC001\\_103A](#). The interrupt service routine associated with this interrupt is responsible for saving the performance information stored in IBS execution registers.

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                                                                |

| 31:16 | <b>IbsTagToRetCtr: micro-op tag to retire count.</b> Read-write; updated-by-hardware. Reset: 0. This field returns the number of cycles from when the micro-op was tagged to when the micro-op was retired. This field is equal to IbsCompToRetCtr when the tagged micro-op is a NOP. |
| 15:0  | <b>IbsCompToRetCtr: micro-op completion to retire count.</b> Read-write; updated-by-hardware. Reset: 0. This field returns the number of cycles from when the micro-op was completed to when the micro-op was retired.                                                                |

### MSRC001\_1036 IBS Op Data 2 (IbsOpData2)

Reset: 0000\_0000h. Northbridge data is only valid for load operations that miss both the L1 data cache and the L2 cache. If a load operation crosses a cache line boundary, the data returned in this register is the data for the access to the lower cache line.

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |      |             |    |                 |    |          |    |                                                       |    |                               |    |                           |    |          |    |          |    |                                                |

### MSRC001\_1037 IBS Op Data 3 (IbsOpData3)

Reset: 0000\_0000\_0000\_0000h. If a load or store operation crosses a 128-bit boundary, the data returned in this register is the data for the access to the data below the 128-bit boundary.

| Bits  | Description                                                                                                                                                                                         |

| 63:48 | <b>IbsTlbRefillLat: L1 DTLB refill latency.</b><br>Read-only. Value: 0.<br>The number of cycles from when a L1 DTLB refill is triggered by a tagged op to when the L1 DTLB fill has been completed. |

| 47:32 | <b>IbsDcMissLat: data cache miss latency.</b> Read-write; updated-by-hardware. Indicates the number of clock cycles from when a miss is detected in the data cache to when the data was delivered to the core. The value returned by this counter is not valid for data cache writes or prefetch instructions.                                                                                                                                                                             |      |             |    |                          |    |      |    |      |    |    |    |    |    |    |       |          |

### 3.23 Core Performance Counter Events

This section provides the core performance counter events that may be selected through [MSRC001\\_020\[A,8,6,4,2,0\]\[EventSelect,UnitMask\]](#). See that register and [MSRC001\\_020\[B,9,7,5,3,1\]](#) [Performance Event Counter (PERF\_CTR[5:0])].

For NB performance counter events see [2.6.1.2 \[NB Performance Monitor Counters\]](#) and [3.24 \[NB Performance Counter Events\]](#).

#### 3.23.1 PMCx0[1F:00] Events (FP)

##### PMCx000 FPU Pipe Assignment

[PERF\\_CTL\[3\]](#). The number of operations (uops) and dual-pipe uops dispatched to each of the 3 FPU execution pipelines. This event reflects how busy the FPU pipelines are and may be used for workload characterization. This includes all operations performed by x87, MMX, and SSE instructions, including moves. Each increment represents a one-cycle dispatch event. This event is a speculative event. (See [PMCx0CB](#)). Since this event includes non-numeric operations it is not suitable for measuring MFLOPS. The number of events logged per cycle can vary from 0 to 6 and must use [PERF\\_CTL\[3\]](#).

| UnitMask | Description                                     |

| 7        | Reserved.                                       |
| 6        | Total number dual-pipe uops assigned to Pipe 2. |
| 5        | Total number dual-pipe uops assigned to Pipe 1. |
| 4        | Total number dual-pipe uops assigned to Pipe 0. |
| 3        | Reserved.                                       |
| 2        | Total number uops assigned to Pipe 2.           |
| 1        | Total number uops assigned to Pipe 1.           |
| 0        | Total number uops assigned to Pipe 0.           |

##### PMCx001 FP Scheduler Empty

[PERF\\_CTL\[5:3\]](#). This is a speculative event. The number of cycles in which the FPU scheduler is empty. Note that some ops like FP loads bypass the scheduler; see the FP MAS for the full list of “no pipe” ops that bypass the scheduler. Invert this ([MSRC001\\_020\[A,8,6,4,2,0\]\[Inv\]==1](#)) to count cycles in which at least one FPU operation is present in the FPU.

##### PMCx003 Retired SSE/AVX Operations

[PERF\\_CTL\[3\]](#). This is a retire-based event. The number of retired SSE/AVX FLOPS. The number of events logged per cycle can vary from 0 to 32.

| UnitMask | Description                                                          |
|----------|----------------------------------------------------------------------|
| 7        | Double precision multiply-add FLOPS. Multiply-add counts as 2 FLOPS. |
| 6        | Double precision divide/square root FLOPS.                           |
| 5        | Double precision multiply FLOPS.                                     |
| 4        | Double precision add/subtract FLOPS.                                 |

|   |                                                                      |
|---|----------------------------------------------------------------------|
| 3 | Single precision multiply-add FLOPS. Multiply-add counts as 2 FLOPS. |
| 2 | Single-precision divide/square root FLOPS.                           |
| 1 | Single-precision multiply FLOPS.                                     |
| 0 | Single-precision add/subtract FLOPS.                                 |

#### PMCx004 Number of Move Elimination and Scalar Op Optimization

[PERF\\_CTL\[3\]](#). This is a dispatch based speculative event, and is useful for measuring the effectiveness of the Move elimination and Scalar code optimization schemes. The number of events logged per cycle can vary from 0 to 8 and must use [PERF\\_CTL\[3\]](#).

| UnitMask | Description                                                                         |
|----------|-------------------------------------------------------------------------------------|
| 7:4      | Reserved.                                                                           |
| 3        | Number of Scalar ops optimized.                                                     |
| 2        | Number of Ops that are candidates for optimization (have Z-bit either set or pass). |
| 1        | Number of SSE Move Ops eliminated.                                                  |
| 0        | Number of SSE Move Ops.                                                             |

#### PMCx005 Retired Serializing Ops

[PERF\\_CTL\[5:3\]](#). The number of serializing ops retired.

| UnitMask | Description                                                                                         |
|----------|-----------------------------------------------------------------------------------------------------|
| 7:4      | Reserved.                                                                                           |
| 3        | x87 control word mispredict traps due to mispredictions in RC or PC, or changes in mask bits.       |
| 2        | x87 bottom-executing uops retired.                                                                  |
| 1        | SSE control word mispredict traps due to mispredictions in RC, FTZ or DAZ, or changes in mask bits. |
| 0        | SSE bottom-executing uops retired.                                                                  |

#### PMCx006 Number of Cycles that a Bottom-Execute uop is in the FP Scheduler

[PERF\\_CTL\[5:3\]](#). This is a speculative event.

### 3.23.2 PMCx0[3F:20] Events (LS)

#### PMCx020 Segment Register Loads

[PERF\\_CTL\[5:0\]](#). The number of segment register loads performed.

| UnitMask | Description |
|----------|-------------|
| 7        | Reserved.   |
| 6        | HS          |
| 5        | GS          |
| 4        | FS          |

|   |    |
|---|----|
| 3 | DS |
| 2 | SS |
| 1 | CS |
| 0 | ES |

#### PMCx021 Pipeline Restart Due to Self-Modifying Code

**PERF\_CTL[5:0]**. The number of pipeline restarts that were caused by self-modifying code (a store that hits any instruction that's been fetched for execution beyond the instruction doing the store).

#### PMCx022 Pipeline Restart Due to Probe Hit

**PERF\_CTL[5:0]**. The number of pipeline restarts caused by an invalidating probe hitting on a speculative out-of-order load.

#### PMCx023 Load Queue/Store Queue Full

**PERF\_CTL[2:0]**. The number of cycles that the load queue(LDQ) or store queue (STQ) is full. The load queue holds loads that missed the data cache and are waiting on a refill; the store queue holds stores waiting to retire. This condition stalls further data cache accesses, although such stalls may be overlapped by independent instruction execution.

| UnitMask | Description                                         |
|----------|-----------------------------------------------------|
| 7:2      | Reserved.                                           |
| 1        | The number of cycles that the store buffer is full. |
| 0        | The number of cycles that the load buffer is full.  |

#### PMCx024 Locked Operations

**PERF\_CTL[5:0]**. This event covers locked operations performed and their non-speculative execution time.

#### PMCx026 Retired CLFLUSH Instructions

**PERF\_CTL[5:0]**. The number of retired CLFLUSH instructions. This is a non-speculative event.

#### PMCx027 Retired CPUID Instructions

**PERF\_CTL[5:0]**. The number of CPUID instructions retired.

#### PMCx029 LS Dispatch

**PERF\_CTL[5:0]**. Counts the number of operations dispatched to the LS unit.

| UnitMask | Description     |
|----------|-----------------|
| 7:3      | Reserved.       |
| 2        | Load-op-Stores. |

|   |         |
|---|---------|
| 1 | Stores. |
| 0 | Loads.  |

### PMCx02A Canceled Store to Load Forward Operations

[PERF\\_CTL\[5:0\]](#). Counts the number of canceled store to load forward operations.

| UnitMask | Description                                                                           |
|----------|---------------------------------------------------------------------------------------|
| 7:2      | Reserved.                                                                             |
| 1        | Physical tag mismatch.                                                                |
| 0        | Either “store is smaller than load” or “different starting byte but partial overlap”. |

### PMCx02B SMIs Received

[PERF\\_CTL\[5:0\]](#). Counts the number of SMIs received.

### PMCx030 Executed CLFLUSH Instructions

[PERF\\_CTL\[5:0\]](#). The number of executed CLFLUSH instructions. This is a speculative event.

### PMCx032 Misaligned Stores

[PERF\\_CTL\[5:0\]](#). The number of misaligned stores.

### PMCx034 FP +Load Buffer Stall

[PERF\\_CTL\[5:0\]](#). The number of loads stalled due to buffer full.

### PMCx035 STLF

[PERF\\_CTL\[5:0\]](#). Number of STLF hits.

## 3.23.3 PMCx0[5F:40] Events (DC)

### PMCx040 Data Cache Accesses

[PERF\\_CTL\[5:0\]](#). The number of accesses to the data cache for load and store references. This may include certain microcode scratchpad accesses, although these are generally rare. This event is a speculative event. The number of events logged per cycle can vary from 0 to 2.

### PMCx041 Data Cache Misses

[PERF\\_CTL\[5:0\]](#). The number of data cache references which missed in the data cache. This event is a speculative event. Only the first miss for a given line is included; access attempts by other instructions while the refill is still pending are not included in this event. Each event reflects one 64 B cache line refill, and counts of this event are the same as, or very close to, the combined count for [PMCx042](#). The number of events logged per

cycle can vary from 0 to 2.

| UnitMask | Description                                                    |
|----------|----------------------------------------------------------------|
| 7:2      | Reserved.                                                      |
| 1        | First streaming store to a 64 B cache line.                    |
| 0        | First data cache miss or streaming store to a 64 B cache line. |

#### PMCx042 Data Cache Refills from L2 or System

[PERF\\_CTL\[5:0\]](#). The number of data cache refills satisfied from the L2 cache and/or the system. Each increment reflects a 64 B transfer. This event is a speculative event.

| UnitMask | Description                                        |
|----------|----------------------------------------------------|
| 7:5      | Reserved.                                          |
| 4        | No-acknowledge fill response.                      |
| 3        | Fill with read data error.                         |
| 2        | Reserved.                                          |
| 1        | Early valid status turned out to be invalid.       |
| 0        | Fill with good data. (Final valid status is valid) |

#### PMCx043 Data Cache Refills from System

[PERF\\_CTL\[2:0\]](#). The number of L1 cache refills satisfied from the system (system memory or another cache), as opposed to the L2. Each increment reflects a 64 B transfer. This event is a speculative event.

#### PMCx045 Unified TLB Hit

[PERF\\_CTL\[2:0\]](#). The number of TLB accesses that miss in the L1 DTLB or L1 and L2 ITLBs and hit in the unified TLB (UCTLB). This event is a speculative event.

| UnitMask | Description                           |
|----------|---------------------------------------|
| 7        | Reserved.                             |
| 6        | 1 GB unified TLB hit for instruction. |
| 5        | 2 MB unified TLB hit for instruction. |
| 4        | 4 KB unified TLB hit for instruction. |
| 3        | Reserved.                             |
| 2        | 1 GB unified TLB hit for data.        |
| 1        | 2 MB unified TLB hit for data.        |
| 0        | 4 KB unified TLB hit for data.        |

**PMCx046 Unified TLB Miss**

**PERF\_CTL[2:0]**. The number of TLB accesses that miss in all TLBs. This event is a speculative event.

| UnitMask | Description                            |
|----------|----------------------------------------|
| 7        | Reserved.                              |
| 6        | 1 GB unified TLB miss for instruction. |
| 5        | 2 MB unified TLB miss for instruction. |
| 4        | 4 KB unified TLB miss for instruction. |
| 3        | Reserved.                              |
| 2        | 1 GB unified TLB miss for data.        |
| 1        | 2 MB unified TLB miss for data.        |
| 0        | 4 KB unified TLB miss for data.        |

**PMCx047 Misaligned Accesses**

**PERF\_CTL[5:0]**. The number of data cache accesses that are misaligned. These are accesses which cross an 8 B boundary. They incur an extra cache access (reflected in **PMCx040**), and an extra cycle of latency on reads. This event is a speculative event.

**PMCx04B Prefetch Instructions Dispatched**

**PERF\_CTL[5:0]**. The number of prefetch instructions dispatched by the decoder. Such instructions may or may not cause a cache line transfer. Any Dcache and L2 accesses, hits and misses by prefetch instructions are included in these types of events. This event is a speculative event.

| UnitMask | Description                       |
|----------|-----------------------------------|
| 7:3      | Reserved.                         |
| 2        | NTA (PrefetchNTA)                 |
| 1        | Store (PrefetchW)                 |
| 0        | Load (Prefetch, PrefetchT0/T1/T2) |

**PMCx052 Ineffective Software Prefetchs**

**PERF\_CTL[5:0]**. The number of software prefetches that did not fetch data outside of the processor core.

| UnitMask | Description                      |
|----------|----------------------------------|
| 7:4      | Reserved.                        |
| 3        | Software prefetch hit in the L2. |
| 2:1      | Reserved.                        |
| 0        | Software prefetch hit in the L1. |

**3.23.4 PMCx[1:0][7F:60] Events (CU)****PMCx060 Command Related to Victim Buffers**[PERF\\_CTL\[2:0\]](#).

| UnitMask | Description          |
|----------|----------------------|
| 7        | Lock                 |
| 6:5      | Reserved.            |
| 4        | Clean Victim Command |
| 3        | Write Victim Block   |
| 2:0      | Reserved.            |

**PMCx061 Command Related to Masked Operations**

[PERF\\_CTL\[2:0\]](#). Count Masked Byte and DW reads and writes to the NB. Byte sized read and write commands can request the transfer of up to 32 bytes. DW sized read and write commands can request the transfer of up to 32 DW's. Combining of the WC memory type can cause 1 B/DW write to represent multiple stores.

| UnitMask | Description       |
|----------|-------------------|
| 7:6      | Reserved.         |

### PMCx064 Dram System Request

[PERF\\_CTL\[2:0\]](#).

### PMCx065 Memory Requests by Type

[PERF\\_CTL\[2:0\]](#). These events reflect accesses to uncacheable (UC), write-combining (WC), and streaming store (SS) activity to WB memory.

| UnitMask | Description                                                                                               |
|----------|-----------------------------------------------------------------------------------------------------------|
| 7        | Requests to non-cacheable (WC+/SS, but not WC) memory, consisting of reads and 64 B sized buffer flushes. |
| 6:2      | Reserved.                                                                                                 |
| 1        | Requests to non-cacheable (WC, but not WC+/SS) memory, consisting of reads and 64 B sized buffer flushes. |
| 0        | Requests to non-cacheable (UC) memory.                                                                    |

### PMCx067 Data Cache Prefetches

| UnitMask | Description        |
|----------|--------------------|
| 7:2      | Reserved.          |
| 1        | Prefetch attempts. |
| 0        | Reserved.          |

### PMCx068 MAB Requests

[PERF\\_CTL\[2:0\]](#). Events [PMCx068](#) and [PMCx069](#) reflect utilization of the Miss Address buffers (MABs), which handle IC, DC, TLB, WCC, and WCB related requests. The UnitMask[BufferID] is an encoded value which selects one of the MABs. [PMCx068](#) counts the number of cacheable L2 misses handled by the selected MAB; [PMCx069](#) counts the number of cycles the selected MAB is busy waiting for the NB response. The average latency seen by the selected MAB is the number of cycles spent waiting ([PMCx069](#)) divided by the number of requests ([PMCx068](#)).

| UnitMask | Description                                                                                                                                                     |      |             |      |        |        |          |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------------|------|--------|--------|----------|

| Bits     | Description                                                                                                                                                     |      |             |      |        |        |          |
| 27-0     | MAB ID                                                                                                                                                          |      |             |      |        |        |          |
| 255-28   | Reserved                                                                                                                                                        |      |             |      |        |        |          |

### PMCx069 MAB Wait Cycles

[PERF\\_CTL\[2:0\]](#).

See [PMCx068](#).

| UnitMask | Description                                                  |
|----------|--------------------------------------------------------------|
| 7:0      | <b>BufferID.</b><br>See: <a href="#">PMCx068</a> [BufferID]. |

### PMCx06C System Response by Coherence State

[PERF\\_CTL\[2:0\]](#). The number of responses from the system for cache refill requests. The UnitMask may be used to select specific cache coherency states. Each increment represents one 64 B cache line transferred from the system (DRAM or another cache, including another core on the same node) to the data cache, instruction cache or L2 cache (for data prefetcher and TLB table walks). Modified-state responses may be for Dcache store miss refills, PrefetchW software prefetches, hardware prefetches for a store-miss stream, or Change-to-Dirty requests that get a dirty (Owned) probe hit in another cache. Exclusive responses may be for any Icache refill, Dcache load miss refill, other software prefetches, hardware prefetches for a load-miss stream, or TLB table walks that miss in the L2 cache; Shared responses may be for any of those that hit a clean line in another cache.

| UnitMask | Description        |
|----------|--------------------|
| 7:6      | Reserved.          |
| 5        | Modified unwritten |
| 4        | Data Error         |
| 3        | Owned              |
| 2        | Shared             |
| 1        | Modified           |
| 0        | Exclusive          |

### PMCx06D Octwords Written to System

[PERF\\_CTL\[2:0\]](#). The number of OW (16 B) data transfers from the processor to the system. These may be part of a 64 B cache line writeback or a 64 B dirty probe hit response, each of which would cause four increments; or a partial or complete Write Combining buffer flush (Sized Write), which could cause from one to four increments.

| UnitMask | Description        |
|----------|--------------------|
| 7:6      | Reserved.          |
| 5:1      | Reserved.          |
| 0        | OW write transfer. |

### PMCx075 Cache Cross-invalidates

These reflect internal probes for Icache or Dcache misses that hit in the Dcache or Icache, causing the line to be

invalidated. These may result from code modification, data being located too close to code, or virtual address aliasing. The aliasing cases arise when a physical memory location is referenced via two or more virtual addresses which differ in bits 14:12. Such aliasing cases are generally uncommon.

| UnitMask | Description                                                                                    |
|----------|------------------------------------------------------------------------------------------------|
| 7:4      | Reserved.                                                                                      |
| 3        | IC Invalidates DC (execution of recently modified code, or modified data too close to code).   |
| 2        | IC Invalidates IC (aliasing)                                                                   |
| 1        | DC Invalidates DC (aliasing)                                                                   |
| 0        | DC Invalidates IC (modification of cached instructions, or of data located too close to code). |

### PMCx076 CPU Clocks not Halted

#### [PERF\\_CTL\[2:0\]](#).

The number of clocks that the CPU is not in a halted state (due to STPCLK or a HLT instruction). Note: this event allows system idle time to be automatically factored out from IPC (or CPI) measurements, providing the OS halts the CPU when going idle. If the OS goes into an idle loop rather than halting, such calculations are influenced by the IPC of the idle loop.

### PMCx07D Requests to L2 Cache

[PERF\\_CTL\[2:0\]](#). The number of requests to the L2 cache for Icache or Dcache fills, or page table lookups for the TLB. These events reflect only read requests to the L2; writes to the L2 are indicated by [PMCx07E](#). See [PMCx081](#), [PMCx082](#), [PMCx083](#), [PMCx041](#), [PMCx042](#), [PMCx043](#).

| UnitMask | Description                 |
|----------|-----------------------------|
| 7        | Reserved.                   |
| 6        | L2 cache prefetcher request |
| 5        | Reserved.                   |
| 4        | Canceled request            |
| 3        | NB probe request            |
| 2        | TLB fill (page table walks) |
| 1        | DC fill                     |
| 0        | IC fill                     |

### PMCx07E L2 Cache Misses

[PERF\\_CTL\[2:0\]](#). The number of requests that miss in the L2 cache. This may include some amount of speculative activity. The IC-fill-miss and DC-fill-miss events tend to mirror the Icache and Dcache refill-from-system [PMCx083](#) and [PMCx043](#), and tend to include more speculative activity than those events.

| UnitMask | Description                 |
|----------|-----------------------------|
| 7:6      | Reserved.                   |
| 5        | Reserved.                   |
| 4        | L2 Cache Prefetcher request |

|   |                                                                               |
|---|-------------------------------------------------------------------------------|
| 3 | Reserved.                                                                     |
| 2 | TLB page table walk                                                           |
| 1 | DC fill (includes possible replays, whereas <a href="#">PMCx041</a> does not) |
| 0 | IC fill                                                                       |

### PMCx07F L2 Fill/Writeback

[PERF\\_CTL\[2:0\]](#). Each increment represents a 64 B cache line transfer.

| UnitMask | Description                                                                                                                                                                        |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:3      | Reserved.                                                                                                                                                                          |
| 2        | <b>L2CleanWritebacks</b> . L2 Clean Writebacks to system                                                                                                                           |
| 1        | <b>L2Writebacks</b> . L2 Writebacks to system (Clean and Dirty)                                                                                                                    |
| 0        | <b>L2Fills</b> . L2 fills from system. Note: Fills for non-temporal software prefetch and WP-memtype fills also are counted in this event even though they don't get cached in L2. |

### PMCx165 Page Splintering

[PERF\\_CTL\[2:0\]](#). Counts the number of TLB reloads where a large page is installed into the TLB as a smaller page size.

| UnitMask | Description                                                                      |
|----------|----------------------------------------------------------------------------------|
| 7:3      | Reserved.                                                                        |
| 2        | Host page size is larger than the guest page size.                               |
| 1        | Splintering due to MTRRs, IORRs, APIC, TOMs or other special address region.     |
| 0        | Guest page size is larger than the host page size when nested paging is enabled. |

### PMCx16C L2 Prefetcher Trigger Events

[PERF\\_CTL\[2:0\]](#).

| UnitMask | Description                       |
|----------|-----------------------------------|
| 7:2      | Reserved.                         |
| 1        | Store L1 miss seen by prefetcher. |
| 0        | Load L1 miss seen by prefetcher.  |

### 3.23.5 PMCx[1:0][9F:80] Events (IC)

Note: All instruction cache events are speculative events unless specified otherwise.

### PMCx080 Instruction Cache Fetches

[PERF\\_CTL\[2:0\]](#).

The number of successful instruction cache accesses by the instruction fetcher that result in data being sent to the decoder. Each access is an aligned 32 byte read, from which a varying number of instructions may be decoded.

**PMCx081 Instruction Cache Misses**[PERF\\_CTL\[2:0\]](#).

The number of instruction fetches and prefetch requests that miss in the instruction cache. This is typically equal to or very close to the sum of events 82h and 83h. Each miss results in a 64-byte cache line refill.

**PMCx082 Instruction Cache Refills from L2**[PERF\\_CTL\[2:0\]](#).

The number of instruction cache refills satisfied from the L2 cache. Each increment represents one 64-byte cache line transfer.

**PMCx083 Instruction Cache Refills from System**[PERF\\_CTL\[2:0\]](#).

The number of instruction cache refills from system memory (or another cache). Each increment represents one 64-byte cache line transfer.

**PMCx084 L1 ITLB Miss, L2 ITLB Hit**[PERF\\_CTL\[2:0\]](#).

The number of instruction fetches that miss in the L1 ITLB but hit in the L2 ITLB.

**PMCx085 L1 ITLB Miss, L2 ITLB Miss**[PERF\\_CTL\[2:0\]](#). The number of instruction fetches that miss in both the L1 and L2 TLBs.

| UnitMask | Description                         |
|----------|-------------------------------------|
| 7:3      | Reserved.                           |
| 2        | Instruction fetches to a 1 GB page. |
| 1        | Instruction fetches to a 2 MB page. |
| 0        | Instruction fetches to a 4 KB page. |

**PMCx086 Pipeline Restart Due to Instruction Stream Probe**

[PERF\\_CTL\[2:0\]](#). The number of pipeline restarts caused by invalidating probes that hit on the instruction stream currently being executed. This would happen if the active instruction stream was being modified by another processor in an MP system - typically a highly unlikely event.

**PMCx087 Instruction Fetch Stall**

[PERF\\_CTL\[2:0\]](#). The number of cycles the instruction fetcher is stalled for the core. This may be for a variety of reasons such as branch predictor updates, unconditional branch bubbles, far jumps and cache misses, instruction fetching for the other core while instruction fetch for this core is stalled, among others. May be overlapped by instruction dispatch stalls or instruction execution, such that these stalls don't necessarily impact performance.

**PMCx088 Return Stack Hits****PERF\_CTL[2:0].**

The number of near return instructions (RET or RET Iw) that get their return address from the return address stack (i.e. where the stack has not gone empty) for the core. This may include cases where the address is incorrect (return mispredicts). This may also include speculatively executed false-path returns. Return mispredicts are typically caused by the return address stack underflowing, however they may also be caused by an imbalance in calls vs. returns, such as doing a call but then popping the return address off the stack.

This event cannot be reliably compared with events C9h and CAh (such as to calculate percentage of return mispredicts due to an empty return address stack), since it may include speculatively executed false-path returns that are not included in those retire-time events.

**PMCx089 Return Stack Overflows**

**PERF\_CTL[2:0].** The number of (near) call instructions that cause the return address stack to overflow. When this happens, the oldest entry is discarded. This count may include speculatively executed calls.

**PMCx08B Instruction Cache Victims**

**PERF\_CTL[2:0].** The number of cachelines evicted from the instruction cache that cause an L2 write due to changed predecode (start bits); the L2 write due to changed predecode doesn't write the instruction bytes. This event does not count IC evictions with unchanged predecode, which are silently dropped without an L2 write. This event is not core specific and for either core counts the IC victims caused by both cores of the compute unit.

**PMCx08C Instruction Cache Lines Invalidated**

**PERF\_CTL[2:0].** The number of instruction cache lines invalidated. A non-SMC event is CMC (cross modifying code), either from the other core of the compute unit or another compute compute unit.

| UnitMask | Description                                                       |
|----------|-------------------------------------------------------------------|
| 7:4      | Reserved.                                                         |
| 3        | SMC invalidating probe that hit on in-flight instructions.        |
| 2        | SMC invalidating probe that missed on in-flight instructions.     |
| 1        | Non-SMC invalidating probe that hit on in-flight instructions.    |
| 0        | Non-SMC invalidating probe that missed on in-flight instructions. |

**PMCx099 ITLB Reloads**

**PERF\_CTL[2:0].** The number of ITLB reload requests.

**PMCx09A ITLB Reloads Aborted**

**PERF\_CTL[2:0].** The number of ITLB reloads aborted.

### PMCx186 Uops Dispatched From Decoder

**PERF\_CTL[2:0]**. Counts uops that are dispatched from the decoder each cycle. The number of events logged per cycle can vary from 0 to 4. Note that when microcode dispatches between 1 to 4 uops in a cycle then 4 uops are counted in that cycle.

| UnitMask | Description                                                                                                                                                                                                                                   |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:1      | Reserved.                                                                                                                                                                                                                                     |
| 0        | <b>UopsDispatched: Uops Dispatched From Decoder.</b><br><b>AllOps.</b> Ops dispatched from the decoder.<br><div> <div>Bits</div> <div>Description</div> </div> <div> <div>0h</div> <div>AllOps: Ops dispatched from the decoder.</div> </div> |

### 3.23.6 PMCx[1,0][DF:C0] Events (EX, DE)

#### PMCx0C0 Retired Instructions

**PERF\_CTL[5:0]**. The number of instructions retired (execution completed and architectural state updated). This count includes exceptions and interrupts - each exception or interrupt is counted as one instruction.

#### PMCx0C1 Retired uops

**PERF\_CTL[5:0]**. The number of micro-ops retired. This includes all processor activity (instructions, exceptions, interrupts, microcode assists, etc.). The number of events logged per cycle can vary from 0 to 4.

#### PMCx0C2 Retired Branch Instructions

**PERF\_CTL[5:0]**. The number of branch instructions retired. This includes all types of architectural control flow changes, including exceptions and interrupts.

#### PMCx0C3 Retired Mispredicted Branch Instructions

**PERF\_CTL[5:0]**. The number of branch instructions retired, of any type, that were not correctly predicted. This includes those for which prediction is not attempted (far control transfers, exceptions and interrupts).

#### PMCx0C4 Retired Taken Branch Instructions

**PERF\_CTL[5:0]**. The number of taken branches that were retired. This includes all types of architectural control flow changes, including exceptions and interrupts.

#### PMCx0C5 Retired Taken Branch Instructions Mispredicted

**PERF\_CTL[5:0]**. The number of retired taken branch instructions that were mispredicted.

#### PMCx0C6 Retired Far Control Transfers

**PERF\_CTL[5:0]**. The number of far control transfers retired including far call/jump/return, IRET, SYSCALL and SYSRET, plus exceptions and interrupts. Far control transfers are not subject to branch prediction.

**PMCx0C7 Retired Branch Resyncs**

[PERF\\_CTL\[5:0\]](#). The number of resync branches. These reflect pipeline restarts due to certain microcode assists and events such as writes to the active instruction stream, among other things. Each occurrence reflects a restart penalty similar to a branch mispredict. This is relatively rare.

**PMCx0C8 Retired Near Returns**

[PERF\\_CTL\[5:0\]](#). The number of near return instructions (RET or RET Iw) retired.

**PMCx0C9 Retired Near Returns Mispredicted**

[PERF\\_CTL\[5:0\]](#). The number of near returns retired that were not correctly predicted by the return address predictor. Each such mispredict incurs the same penalty as a mispredicted conditional branch instruction.

**PMCx0CA Retired Mispredicted Taken Branch Instructions due to Target Mismatch**

[PERF\\_CTL\[5:0\]](#). The number of indirect branch instructions retired where the target address was not correctly predicted.

**PMCx0CB Retired MMX/FP Instructions**

[PERF\\_CTL\[5:0\]](#). The number of MMX, SSE or x87 instructions retired. The UnitMask allows the selection of the individual classes of instructions as given in the table. Each increment represents one complete instruction. Since this event includes non-numeric instructions it is not suitable for measuring MFLOPS.

| UnitMask | Description                                                                      |
|----------|----------------------------------------------------------------------------------|
| 7:3      | Reserved.                                                                        |
| 2        | SSE instructions (SSE, SSE2, SSE3, SSSE3, SSE4A, SSE4.1, SSE4.2, AVX, XOP, FMA4) |
| 1        | MMX™ instructions.                                                               |
| 0        | x87 instructions.                                                                |

**PMCx0CD Interrupts-Masked Cycles**

[PERF\\_CTL\[5:0\]](#). The number of cycles where interrupts are masked (EFLAGS.IF = 0). Using edge-counting with this event gives the number of times IF is cleared; dividing the cycle-count value by this value gives the average length of time that interrupts are disabled on each instance. Compare the edge count with [PMCx0CF](#) to determine how often interrupts are disabled for interrupt handling vs. other reasons (e.g. critical sections).

**PMCx0CE Interrupts-Masked Cycles with Interrupt Pending**

[PERF\\_CTL\[5:0\]](#). The number of cycles where interrupts are masked (EFLAGS.IF = 0) and an interrupt is pending. Using edge-counting with this event and comparing the resulting count with the edge count for [PMCx0CD](#) gives the proportion of interrupts for which handling is delayed due to prior interrupts being serviced, critical sections, etc. The cycle count value gives the total amount of time for such delays. The cycle count divided by the edge count gives the average length of each such delay.

**PMCx0CF Interrupts Taken**

---

[PERF\\_CTL\[5:0\]](#). The number of hardware interrupts taken. This does not include software interrupts (INT n instruction).

**PMCx0D0 Decoder Empty**

---

[PERF\\_CTL\[2:0\]](#). The number of cycles where the decoder has nothing to dispatch (typically waiting on an instruction fetch that missed the Icache, or for the target fetch after a branch mispredict).

**PMCx0D1 Dispatch Stalls**

---

[PERF\\_CTL\[2:0\]](#). The number of cycles where the decoder is stalled for any reason (has one or more instructions ready but can't dispatch them due to resource limitations in execution). This event counts even when dispatch selects the other core of the compute-unit. This is the combined effect of events [PMCx0D3](#) to [PMCx0D9](#), some of which may overlap; this event reflects the net stall cycles. The more common stall conditions (events [PMCx0D5](#), [PMCx0D6](#), [PMCx0D7](#), [PMCx0D8](#)) may overlap considerably. The occurrence of these stalls is highly dependent on the nature of the code being executed (instruction mix, memory reference patterns, etc.).

**PMCx0D3 Microsequencer Stall due to Serialization**

---

[PERF\\_CTL\[2:0\]](#). The number of cycles the microsequencer is stalled due to a serializing operation, which waits for the execution pipeline to drain. Relatively rare; mainly associated with system instructions. See [PMCx0D1](#).

**PMCx0D5 Dispatch Stall for Instruction Retire Queue Full**

---

[PERF\\_CTL\[2:0\]](#). The number of cycles the decoder is stalled because the instruction retire Q is full. This event counts even when dispatch selects the other core of the compute-unit. May occur simultaneously with certain other stall conditions; see [PMCx0D1](#).

**PMCx0D6 Dispatch Stall for Integer Scheduler Queue Full**

---

[PERF\\_CTL\[2:0\]](#). The number of cycles the decoder is stalled because a required integer unit scheduler queue is full. This event counts even when dispatch selects the other core of the compute-unit. May occur simultaneously with certain other stall conditions; see [PMCx0D1](#).

**PMCx0D7 Dispatch Stall for FP Scheduler Queue Full**

---

[PERF\\_CTL\[2:0\]](#). The number of cycles the decoder is stalled because the scheduler for the Floating Point scheduler queue is full. This event counts even when dispatch selects the other core of the compute-unit. This condition can be caused by a lack of parallelism in FP-intensive code, or by cache misses on FP operand loads (which could also show up as [PMCx0D8](#) instead, depending on the nature of the instruction sequences). May occur simultaneously with certain other stall conditions; see [PMCx0D1](#).

**PMCx0D8 Dispatch Stall for LDQ Full**

---

[PERF\\_CTL\[2:0\]](#). The number of cycles the decoder is stalled because the load queue is full. This event counts

even when dispatch selects the other core of the compute-unit. This generally occurs due to heavy cache miss activity. May occur simultaneously with certain other stall conditions; see [PMCx0D1](#).

### PMCx0D9 Microsequencer Stall Waiting for All Quiet

[PERF\\_CTL\[2:0\]](#). The number of cycles the microsequencer is stalled waiting for all outstanding requests to the system to be resolved. Relatively rare; associated with certain system instructions and types of interrupts. May partially overlap certain other stall conditions; see [PMCx0D1](#).

### PMCx0DB FPU Exceptions

[PERF\\_CTL\[5:0\]](#). The number of floating point unit exceptions for microcode assists. The UnitMask may be used to isolate specific types of exceptions.

| UnitMask | Description       |
|----------|-------------------|
| 7:5      | Reserved.         |
| 4        | Bypass faults     |
| 3        | Ext2Int faults    |
| 2        | Int2Ext faults    |
| 1        | Total microtraps  |
| 0        | Total microfaults |

### PMCx0D[F:C] DR[3:0] Breakpoint Matches

[PERF\\_CTL\[5:0\]](#).

Table 257: [Register Mapping](#) for [PMCx0D\[F:C\]](#)

| Register | Function |
|----------|----------|
| PMCx0DC  | DR0      |
| PMCx0DD  | DR1      |
| PMCx0DE  | DR2      |
| PMCx0DF  | DR3      |

The number of matches on the address in breakpoint register DR[3:0], per the breakpoint type specified in DR7. Matches occur if the access becomes non-speculative, but not necessarily retired. Each instruction breakpoint match incurs an overhead of about 120 cycles; load/store breakpoint matches do not incur any overhead.

### PMCx1C0 Retired x87 Floating Point Operations

[PERF\\_CTL\[5:3\]](#). The number of x87 floating point ops that have retired.

| UnitMask | Description                |
|----------|----------------------------|
| 7:3      | Reserved.                  |
| 2        | Divide and square root ops |

|   |                  |
|---|------------------|
| 1 | Multiply ops     |
| 0 | Add/subtract ops |

### PMCx1CF Tagged IBS Ops

[PERF\\_CTL\[5:0\]](#).

| UnitMask | Description                                                                                            |
|----------|--------------------------------------------------------------------------------------------------------|
| 7:3      | Reserved.                                                                                              |
| 2        | Number of times an op could not be tagged by IBS because of a previous tagged op that has not retired. |
| 1        | Number of ops tagged by IBS that retired.                                                              |
| 0        | Number of ops tagged by IBS.                                                                           |

### PMCx1D0 Retired Fused Branch Instructions

[PERF\\_CTL\[5:0\]](#). Implemented by EX. The number of fused retired branch instructions retired per cycle. The number of events logged per cycle can vary from 0 to 3.

### PMCx1D8 Dispatch Stall for STQ Full

[PERF\\_CTL\[5:0\]](#). The number of cycles the decoder is stalled because the store queue is full. This event counts even when dispatch selects the other core of the compute-unit. This generally occurs due to heavy cache miss activity. May occur simultaneously with certain other stall conditions.

### PMCx1DD Cycles Without Dispatch Due To Integer PRF Tokens

[PERF\\_CTL\[2:0\]](#). The number of cycles a core has valid ops for dispatch and one of the reasons for a dispatch stall is the absence of sufficient integer PRF tokens. This event counts even when dispatch selects the other core of the compute-unit.

### PMCx1DE Cycles Without Dispatch Due to FP PRF Tokens

[PERF\\_CTL\[2:0\]](#). The number of cycles a core has valid ops for dispatch and one of the reasons for a dispatch stall is the absence of sufficient FP PRF tokens. This event requires that the other core of the compute unit is in the Halt state. This event counts even when dispatch selects the other core of the compute-unit.

### PMCx1DF FP Dispatch Contention

[PERF\\_CTL\[2:0\]](#). Cycles in which there is contention between the two threads for FP dispatch.

| UnitMask | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |      |             |     |                                                                                                 |     |                                                                                             |     |                                                                                             |     |                                                                                         |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------------|-----|-------------------------------------------------------------------------------------------------|-----|---------------------------------------------------------------------------------------------|-----|---------------------------------------------------------------------------------------------|-----|-----------------------------------------------------------------------------------------|
| 7:2      | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |      |             |     |                                                                                                 |     |                                                                                             |     |                                                                                             |     |                                                                                         |

|-----|-----------------------------------------------|
| 2   | Number of times the HTC trip point is crossed |
| 1:0 | Reserved                                      |

### NBPMCx0E9 CPU/IO Requests to Memory/IO

These events reflect request flow between units and nodes, as selected by the UnitMask. The UnitMask is divided into two fields: request type (CPU or IO access to IO or Memory) and source/target location (local vs. remote). One or more requests types must be enabled via bits 3:0, and at least one source and one target location must be selected via bits 7:4. Each event reflects a request of the selected type(s) going from the selected source(s) to the selected target(s).

Not all possible paths are supported. The following table shows the UnitMask values that are valid for each request type:

| Source/Target    | CPU to Mem | CPU to IO | IO to Mem | IO to IO |
|------------------|------------|-----------|-----------|----------|
| Local -> Local   | A8h        | A4h       | A2h       | A1h      |
| Local -> Remote  | 98h        | 94h       | 92h       | 91h      |
| Remote -> Local  | -          | 64h       | -         | 61h      |
| Remote -> Remote | -          | -         | -         | -        |

Any of the mask values shown may be logically ORed to combine the events. For instance, local CPU requests to both local and remote nodes would be  $A8h \mid 98h = B8h$ . Any CPU to any IO would be  $A4h \mid 94h \mid 64h = F4h$  (but remote CPU to remote IO requests would not be included).

Note: It is not possible to tell from these events how much data is going in which direction, as there is no distinction between reads and writes. Also, particularly for IO, the requests may be for varying amounts of data, anywhere from one to sixty-four bytes. For a direct measure of the amount and direction of data flowing between nodes, use events F6h, F7h and F8h.

| UnitMask | Description      |
|----------|------------------|
| 7        | From local node  |
| 6        | From remote node |
| 5        | To local node    |
| 4        | To remote node   |
| 3        | CPU to Mem       |
| 2        | CPU to IO        |
| 1        | IO to Mem        |
| 0        | IO to IO         |

### NBPMCx0EA Cache Block Commands

The number of requests made to the system for cache line transfers or coherency state changes, by request type. Each increment represents one cache line transfer, except for Change-to-Dirty. If a Change-to-Dirty request hits on a line in another processor's cache that's in the Owned state, it causes a cache line transfer, otherwise there is no data transfer associated with Change-to-Dirty requests.

| UnitMask | Description                                                   |
|----------|---------------------------------------------------------------|
| 7:6      | Reserved.                                                     |
| 5        | Change-to-Dirty (first store to clean block already in cache) |
| 4        | Read Block Modified (Dcache store miss refill)                |
| 3        | Read Block Shared (Icache refill)                             |
| 2        | Read Block (Dcache load miss refill)                          |
| 1        | Reserved.                                                     |
| 0        | Victim Block (Writeback)                                      |

### NBPMCx0EB Sized Commands

The number of Sized Read/Write commands handled by the System Request Interface (local processor and hostbridge interface to the system). These commands may originate from the processor or hostbridge. Typical uses of the various Sized Read/Write commands are given in the UnitMask table. See [NBPMCx0EC](#), which provides a separate measure of Hostbridge accesses.

| UnitMask | Description                                                                                                                                    |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:6      | Reserved.                                                                                                                                      |
| 5        | SzRd DW (1-16 DWORDs). Typical Usage: Block-oriented DMA reads, typically cache-line size.                                                     |
| 4        | SzRd Byte (4 bytes). Typical Usage: Legacy or mapped IO.                                                                                       |
| 3        | Posted SzWr DW (1-16 DWORDs). Typical Usage: Block-oriented DMA writes, often cache-line sized; also processor Write Combining buffer flushes. |
| 2        | Posted SzWr Byte (1-32 bytes). Typical Usage: Sub-cache-line DMA writes, size varies; also flushes of partially-filled Write Combining buffer. |
| 1        | Non-Posted SzWr DW (1-16 DWORDs). Typical Usage: Legacy or mapped IO, typically 1 DWORD.                                                       |
| 0        | Non-Posted SzWr Byte (1-32 bytes). Typical Usage: Legacy or mapped IO, typically 1-4 bytes.                                                    |

### NBPMCx0EC Probe Responses and Upstream Requests

This covers two unrelated sets of events: cache probe results, and requests received by the hostbridge from devices on non-coherent links.

**Probe results:** These events reflect the results of probes sent from a memory controller to local caches. They provide an indication of the degree data and code is shared between processors (or moved between processors due to process migration). The dirty-hit events indicate the transfer of a 64-byte cache line to the requestor (for a read or cache refill) or the target memory (for a write). The system bandwidth used by these, in terms of bytes per unit of time, may be calculated as 64 times the event count, divided by the elapsed time. Sized writes to memory that cover a full cache line do not incur this cache line transfer -- they simply invalidate the line and are reported as clean hits. Cache line transfers occur for Change2Dirty requests that hit cache lines in the Owned state. (Such cache lines are counted as Modified-state refills for [PMCx06C](#), System Read Responses.)

**Upstream requests:** The upstream read and write events reflect requests originating from a device on a local IO link.

| UnitMask | Description                                                                     |
|----------|---------------------------------------------------------------------------------|
| 7        | Upstream non-ISOC writes                                                        |
| 6        | Upstream ISOC writes                                                            |
| 5        | Upstream non-display refresh reads                                              |
| 4        | Upstream display refresh/ISOC reads                                             |
| 3        | Probe hit dirty with memory cancel (probed by DMA read or cache refill request) |
| 2        | Probe hit dirty without memory cancel (probed by Sized Write or Change2Dirty)   |
| 1        | Probe hit clean                                                                 |
| 0        | Probe miss                                                                      |

### 3.24.3 PMCx0F[F:0] Events (Crossbar)

### 3.24.4 NBPMCx1E[F:0] Events (Crossbar)

#### NBPMCx1E0 CPU to DRAM Requests to Target Node

This event counts all DRAM reads and writes generated by cores on the local node to the targeted node in the coherent fabric. This counter can be used to observe processor data affinity in NUMA aware operating systems.

| UnitMask | Description               |
|----------|---------------------------|
| 7        | From Local node to Node 7 |
| 6        | From Local node to Node 6 |
| 5        | From Local node to Node 5 |
| 4        | From Local node to Node 4 |
| 3        | From Local node to Node 3 |
| 2        | From Local node to Node 2 |
| 1        | From Local node to Node 1 |
| 0        | From Local node to Node 0 |

#### NBPMCx1E1 IO to DRAM Requests to Target Node

This event counts all DRAM reads and writes generated by IO devices attached to the IO links of the local node the targeted node in the coherent fabric. This counter can be used to observe IO device data affinity in NUMA aware operating systems.

| UnitMask | Description               |
|----------|---------------------------|
| 7        | From Local node to Node 7 |
| 6        | From Local node to Node 6 |
| 5        | From Local node to Node 5 |
| 4        | From Local node to Node 4 |
| 3        | From Local node to Node 3 |
| 2        | From Local node to Node 2 |

|   |                           |
|---|---------------------------|
| 1 | From Local node to Node 1 |
| 0 | From Local node to Node 0 |

### NBPMCx1E2 CPU Read Command Latency to Target Node 0-3

This event counts the number of NB clocks from when the targeted command is received in the NB to when the targeted command completes. This event only tracks one outstanding command at a time. To determine latency between the local node and a remote node set UnitMask[7:4] to select the node and UnitMask[3:0] to select the read command type. The count returned by the counter should be divided by the count returned by [NBPMCx1E3](#) to determine the average latency for the command type.

| UnitMask | Description               |
|----------|---------------------------|
| 7        | From Local node to Node 3 |
| 6        | From Local node to Node 2 |
| 5        | From Local node to Node 1 |
| 4        | From Local node to Node 0 |
| 3        | Change-to-Dirty           |
| 2        | Read block modified       |
| 1        | Read block shared         |
| 0        | Read block                |

### NBPMCx1E3 CPU Read Command Requests to Target Node 0-3

This event counts the number of requests that a latency measurement is made for using [NBPMCx1E2](#). To determine the number of commands that a latency measurement are made for between the local node and a remote node set UnitMask[7:4] to select the node and UnitMask[3:0] to select the read command type.

| UnitMask | Description               |
|----------|---------------------------|
| 7        | From Local node to Node 3 |
| 6        | From Local node to Node 2 |
| 5        | From Local node to Node 1 |
| 4        | From Local node to Node 0 |
| 3        | Change-to-Dirty           |
| 2        | Read block modified       |
| 1        | Read block shared         |
| 0        | Read block                |

### NBPMCx1E4 CPU Read Command Latency to Target Node 4-7

This event counts the number of NB clocks from when the targeted command is received in the NB to when the targeted command completes. This event only tracks one outstanding command at a time. To determine latency between the local node and a remote node set UnitMask[7:4] to select the node and UnitMask[3:0] to select the read command type. The count returned by the counter should be divided by the count returned by [NBPMCx1E5](#) to determine the average latency for the command type.

| UnitMask | Description               |
|----------|---------------------------|
| 7        | From Local node to Node 7 |
| 6        | From Local node to Node 6 |
| 5        | From Local node to Node 5 |
| 4        | From Local node to Node 4 |
| 3        | Change-to-Dirty           |
| 2        | Read block modified       |
| 1        | Read block shared         |
| 0        | Read block                |

#### **NBPMCx1E5 CPU Read Command Requests to Target Node 4-7**

This event counts the number of requests that a latency measurement is made for using [NBPMCx1E4](#). To determine the number of commands that a latency measurement are made for between the local node and a remote node set UnitMask[7:4] to select the node and UnitMask[3:0] to select the read command type.

| UnitMask | Description               |
|----------|---------------------------|
| 7        | From Local node to Node 7 |
| 6        | From Local node to Node 6 |
| 5        | From Local node to Node 5 |
| 4        | From Local node to Node 4 |
| 3        | Change-to-Dirty           |
| 2        | Read block modified       |
| 1        | Read block shared         |
| 0        | Read block                |

#### **NBPMCx1E6 CPU Command Latency to Target Node 0-3/4-7**

This event counts the number of NB clocks from when the targeted command is received in the NB to when the targeted command completes. This event only tracks one outstanding command at a time. To determine latency between the local node and a remote node set UnitMask[7:4] to select the node, UnitMask[3] to select the node group and UnitMask[3:0] to select the command type. The count returned by the counter should be divided by the count returned by [NBPMCx1E7](#) to determine the average latency for the command type.

| UnitMask | Description                                   |
|----------|-----------------------------------------------|
| 7        | From Local node to Node 3/7                   |
| 6        | From Local node to Node 2/6                   |
| 5        | From Local node to Node 1/5                   |
| 4        | From Local node to Node 0/4                   |
| 3        | Node Group Select. 0=Nodes 0-3. 1= Nodes 4-7. |
| 2        | Victim Block                                  |
| 1        | Write Sized                                   |
| 0        | Read Sized                                    |

### NBPMCx1E7 CPU Requests to Target Node 0-3/4-7

This event counts the number of requests that a latency measurement is made for using [NBPMCx1E6](#). To determine the number of commands that a latency measurement are made for between the local node and a remote node set UnitMask[7:4] to select the node, UnitMask[3] to select the node group and UnitMask[3:0] to select the command type.

| UnitMask | Description                                   |
|----------|-----------------------------------------------|
| 7        | From Local node to Node 3/7                   |
| 6        | From Local node to Node 2/6                   |
| 5        | From Local node to Node 1/5                   |
| 4        | From Local node to Node 0/4                   |
| 3        | Node Group Select. 0=Nodes 0-3. 1= Nodes 4-7. |
| 2        | Victim Block                                  |
| 1        | Write Sized                                   |
| 0        | Read Sized                                    |

### NBPMCx1EB Request Cache Status 1

The probe response type for RdBlkM or ChgToDirty request type.

| UnitMask | Description                     |
|----------|---------------------------------|
| 7        | Track Cache Stat for RdBlkM     |
| 6        | Track Cache Stat for ChgToDirty |
| 5        | Directed Probe                  |
| 4        | Probe Miss                      |
| 3        | Probe Hit M                     |
| 2        | Probe Hit MuW or O              |
| 1        | Probe Hit E                     |
| 0        | Probe Hit S                     |

### 3.24.5 NBPMCx1F[F:0] Events (Memory Controller, Crossbar)

#### NBPMCx1F0 Memory Controller Requests

Read/Write requests: The read/write request events reflect the total number of commands sent to the DRAM controller.

Sized Read/Write activity: The Sized Read/Write events reflect 32- or 64-byte transfers (as opposed to other sizes which could be anywhere between 1 and 64 bytes), from either the processor or the Hostbridge (on any node in an MP system). Such accesses from the processor would be due only to write combining buffer flushes, where 32-byte accesses would reflect flushes of partially-filled buffers. [PMCx065](#) provides a count of sized write requests associated with WC buffer flushes; comparing that with counts for these events (providing there is very little Hostbridge activity at the same time) gives an indication of how efficiently the write combining buffers are being used. [PMCx065](#) may also be useful in factoring out WC flushes when comparing these events with the Upstream Requests component of [PMCx06C](#).

| UnitMask | Description                                                                |
|----------|----------------------------------------------------------------------------|
| 7        | Read requests sent to the DCT while writes requests are pending in the DCT |
| 6        | 64 Byte Sized Reads                                                        |
| 5        | 32 Bytes Sized Reads                                                       |
| 4        | 64 Bytes Sized Writes                                                      |
| 3        | 32 Bytes Sized Writes                                                      |
| 2        | Prefetch requests sent to the DCT                                          |
| 1        | Read requests (including prefetch requests) sent to the DCT                |
| 0        | Write requests sent to the DCT                                             |

### NBPMCx3EC DRAM Accesses

The number of memory accesses performed by the local DRAM controller. UnitMask[7:0] may be used to isolate the different DRAM page access cases. Page miss cases incur an extra latency to open a page; page conflict cases incur both a page-close as well as page-open penalties. These penalties may be overlapped by DRAM accesses for other requests and don't necessarily represent lost DRAM bandwidth. The associated penalties are as follows:

Page miss:  $T_{rd}$  (DRAM RAS-to-CAS delay)

Page conflict:  $T_{rp} + T_{rd}$  (DRAM row-precharge time plus RAS-to-CAS delay)

Each DRAM access represents one 64-byte block of data transferred if the DRAM is configured for 64-byte granularity, or one 32-byte block if the DRAM is configured for 32-byte granularity. (The latter is only applicable to single-channel DRAM systems, which may be configured either way.)

| UnitMask | Description        |
|----------|--------------------|
| 7:6      | Reserved.          |
| 5        | DCT1 Page Conflict |
| 4        | DCT1 Page Miss     |
| 3        | DCT1 Page hit      |
| 2        | DCT0 Page Conflict |
| 1        | DCT0 Page Miss     |
| 0        | DCT0 Page hit      |

### NBPMCx3ED DRAM Controller Page Table Overflows

The number of page table overflows in the local DRAM controller. This table maintains information about which DRAM pages are open. An overflow occurs when a request for a new page arrives when the maximum number of pages are already open. Each occurrence reflects an access latency penalty equivalent to a page conflict.

| UnitMask | Description |
|----------|-------------|
| 7:2      | Reserved.   |

|   |                          |
|---|--------------------------|
| 1 | DCT1 Page Table Overflow |
| 0 | DCT0 Page Table Overflow |

### NBPMCx3EE Memory Controller DRAM Command Slots Missed

| UnitMask | Description                            |
|----------|----------------------------------------|
| 7:2      | Reserved.                              |
| 1        | DCT1 Command Slots Missed (in MEMCLKs) |
| 0        | DCT0 Command Slots Missed (in MEMCLKs) |

### NBPMCx3EF Memory Controller Turnarounds

The number of turnarounds on the local DRAM data bus. UnitMask[7:0] may be used to isolate the different cases. These represent lost DRAM bandwidth, which may be calculated as follows (in bytes per occurrence):

DIMM turnaround:  $\text{DRAM\_width\_in\_bytes} * 2 \text{ edges\_per\_memclk} * 2$   
 R/W turnaround:  $\text{DRAM\_width\_in\_bytes} * 2 \text{ edges\_per\_memclk} * 1$   
 R/W turnaround:  $\text{DRAM\_width\_in\_bytes} * 2 \text{ edges\_per\_memclk} * (\text{Tcl}-1)$

where DRAM\_width\_in\_bytes is 8 or 16 (for single- or dual-channel systems), and Tcl is the CAS latency of the DRAM in memory system clock cycles (where the memory clock for DDR-400, or PC3200 DIMMS, for example, would be 200 MHz).

| UnitMask | Description                        |
|----------|------------------------------------|
| 7:6      | Reserved.                          |
| 5        | DCT1 Write to read turnaround      |
| 4        | DCT1 Read to write turnaround      |
| 3        | DCT1 DIMM (chip select) turnaround |
| 2        | DCT0 Write to read turnaround      |
| 1        | DCT0 Read to write turnaround      |
| 0        | DCT0 DIMM (chip select) turnaround |

### 3.24.6 3F[F:0] Events (Memory Controller)

#### NBPMCx3FC DRAM Accesses

The number of memory accesses performed by the local DRAM controller. UnitMask[7:0] may be used to isolate the different DRAM page access cases. Page miss cases incur an extra latency to open a page; page conflict cases incur both a page-close as well as page-open penalties. These penalties may be overlapped by DRAM accesses for other requests and don't necessarily represent lost DRAM bandwidth. The associated penalties are as follows:

Page miss: Trcd (DRAM RAS-to-CAS delay)  
 Page conflict: Trp + Trcd (DRAM row-precharge time plus RAS-to-CAS delay)

Each DRAM access represents one 64-byte block of data transferred if the DRAM is configured for 64-byte granularity, or one 32-byte block if the DRAM is configured for 32-byte granularity. (The latter is only applicable to single-channel DRAM systems, which may be configured either way.)

| UnitMask | Description        |
|----------|--------------------|
| 7:6      | Reserved.          |
| 5        | DCT3 Page Conflict |
| 4        | DCT3 Page Miss     |
| 3        | DCT3 Page hit      |
| 2        | DCT2 Page Conflict |
| 1        | DCT2 Page Miss     |
| 0        | DCT2 Page hit      |

### NBPMCx3FD DRAM Controller Page Table Overflows

The number of page table overflows in the local DRAM controller. This table maintains information about which DRAM pages are open. An overflow occurs when a request for a new page arrives when the maximum number of pages are already open. Each occurrence reflects an access latency penalty equivalent to a page conflict.

| UnitMask | Description              |
|----------|--------------------------|
| 7:2      | Reserved.                |
| 1        | DCT3 Page Table Overflow |
| 0        | DCT2 Page Table Overflow |

### NBPMCx3FE Memory Controller DRAM Command Slots Missed

| UnitMask | Description                            |
|----------|----------------------------------------|
| 7:2      | Reserved.                              |
| 1        | DCT3 Command Slots Missed (in MEMCLKs) |
| 0        | DCT2 Command Slots Missed (in MEMCLKs) |

### NBPMCx3FF Memory Controller Turnarounds

The number of turnarounds on the local DRAM data bus. UnitMask[7:0] may be used to isolate the different cases. These represent lost DRAM bandwidth, which may be calculated as follows (in bytes per occurrence):

DIMM turnaround:  $\text{DRAM\_width\_in\_bytes} * 2 \text{ edges\_per\_memclk} * 2$   
 R/W turnaround:  $\text{DRAM\_width\_in\_bytes} * 2 \text{ edges\_per\_memclk} * 1$   
 R/W turnaround:  $\text{DRAM\_width\_in\_bytes} * 2 \text{ edges\_per\_memclk} * (\text{Tcl}-1)$

where DRAM\_width\_in\_bytes is 8 or 16 (for single- or dual-channel systems), and Tcl is the CAS latency of the DRAM in memory system clock cycles (where the memory clock for DDR-400, or PC3200 DIMMS, for example, would be 200 MHz).

| UnitMask | Description                        |
|----------|------------------------------------|
| 7:6      | Reserved.                          |
| 5        | DCT3 Write to read turnaround      |
| 4        | DCT3 Read to write turnaround      |
| 3        | DCT3 DIMM (chip select) turnaround |
| 2        | DCT2 Write to read turnaround      |
| 1        | DCT2 Read to write turnaround      |
| 0        | DCT2 DIMM (chip select) turnaround |

## 4 Register List

The following is a list of all storage elements, context, and registers provided in this document. Page numbers, register mnemonics, and register names are provided.

|     |                                                     |     |                                                                                       |
|-----|-----------------------------------------------------|-----|---------------------------------------------------------------------------------------|
| 45  | SMMFEC0: SMM IO Trap Offset                         | 192 | D0F0xBC_x3F800: FIRMWARE_FLAGS                                                        |
| 46  | SMMFEC4: Local SMI Status                           | 192 | D0F0xBC_x3F804: FIRMWARE_VID                                                          |
| 46  | SMMFEC8: SMM IO Restart Byte                        | 192 | D0F0xBC_x3F820: PM_INTERVAL_CNTL_0                                                    |
| 47  | SMMFEC9: Auto Halt Restart Offset                   | 193 | D0F0xBC_x3F828: PM_TIMER_PERIOD                                                       |
| 47  | SMMFECA: NMI Mask                                   | 193 | D0F0xBC_x3F9E8: NB_DPM_CONFIG_1                                                       |
| 47  | SMMFED8: SMM SVM State                              | 193 | D0F0xBC_x3F9EC: NB_DPM_CONFIG_2                                                       |
| 48  | SMMFEFC: SMM-Revision Identifier                    | 194 | D0F0xBC_x3FD[8C:00:step14]: LCLK DPM Control 0                                        |
| 48  | SMMFF00: SMM Base Address (SMM_BASE)                | 194 | D0F0xBC_x3FD[94:08:step14]: LCLK DPM Control 2                                        |
| 177 | IOCF8: IO-Space Configuration Address               | 194 | D0F0xBC_x3FD[9C:10:step14]: LCLK DPM Activity Thresholds                              |
| 178 | IOCF8: IO-Space Configuration Data Port             | 195 | D0F0xBC_x3FDC8: SMU_LCLK_DPM_CNTL                                                     |
| 179 | D0F0x00: Device/Vendor ID                           | 195 | D0F0xBC_x3FDD0: SMU_LCLK_DPM_THERMAL_THROTTLING_CNTL                                  |
| 179 | D0F0x04: Status/Command                             | 195 | D0F0xBC_x3FDD4: SMU_LCLK_DPM_THERMAL_THROTTLING_THRESHOLDS                            |
| 179 | D0F0x08: Class Code/Revision ID                     | 195 | D0F0xBC_xC010_40A0: SVI Loadline Configuration                                        |
| 179 | D0F0x0C: Header Type                                | 196 | D0F0xBC_xC020_0110: Activity Monitor Control                                          |
| 180 | D0F0x2C: Subsystem and Subvendor ID                 | 196 | D0F0xBC_xC210_0000: CPU Interrupt Request                                             |
| 180 | D0F0x34: Capabilities Pointer                       | 196 | D0F0xBC_xC210_0004: CPU Interrupt Status                                              |
| 180 | D0F0x48: NB Header Write Register                   | 197 | D0F0xBC_xC210_003C: CPU Interrupt Argument                                            |
| 180 | D0F0x4C: PCI Control                                | 197 | D0F0xBC_xC210_0040: CPU Interrupt Response                                            |
| 181 | D0F0x60: Miscellaneous Index                        | 197 | D0F0xBC_xE000_3040: CONNECTED_STANDBY_CONTROL                                         |
| 181 | D0F0x64: Miscellaneous Index Data                   | 197 | D0F0xC8: DEV Index Address                                                            |
| 181 | D0F0x64_x00: Northbridge Control                    | 197 | D0F0xCC: DEV Index Data                                                               |
| 181 | D0F0x64_x0C: IOC Bridge Control                     | 198 | D0F0xCC_x01_ib[21,1D:19,12:11]: IOC Bridge Control                                    |
| 181 | D0F0x64_x0D: IOC PCI Configuration                  | 198 | D0F0xCC_x02_ib[21,1D:19,12:11]: IOC Bridge Status                                     |
| 182 | D0F0x64_x16: IOC Advanced Error Reporting Control   | 198 | D0F0xD0: GBIF Index Address                                                           |
| 182 | D0F0x64_x17: Memory Mapped IO Base Address          | 199 | D0F0xD4: GBIF Index Data                                                              |
| 182 | D0F0x64_x18: Memory Mapped IO Limit                 | 199 | D0F0xD4_x0109_14E1: CC Bif Bx Strap0 Ind                                              |
| 182 | D0F0x64_x19: Top of Memory 2 Low                    | 199 | D0F0xD4_x0109_14E2: CC Bif Bx Strap1 Ind                                              |
| 182 | D0F0x64_x1A: Top of Memory 2 High                   | 199 | D0F0xD4_x0109_1507: CC Bif Bx Pinstrap0 Ind                                           |
| 183 | D0F0x64_x1D: Internal Graphics PCI Control          | 200 | D0F0xE0: Link Index Address                                                           |
| 183 | D0F0x64_x1F: FCH Location                           | 201 | D0F0xE4: Link Index Data                                                              |
| 183 | D0F0x64_x22: LCLK Control 0                         | 201 | D0F0xE4_x0[210,11[3:0]]_0010: PIF Control                                             |
| 184 | D0F0x64_x23: LCLK Control 1                         | 201 | D0F0xE4_x0[210,11[3:0]]_0011: PIF Pairing                                             |
| 184 | D0F0x64_x3[B:0]: Programmable Device Remap Register | 202 | D0F0xE4_x0[210,11[3:0]]_001[8:7,3:2]: PIF Power Down Control [3:0]                    |
| 185 | D0F0x64_x46: IOC Features Control                   | 204 | D0F0xE4_x0[220,123:120]_0000: Phy Compensation Control and Calibration Control I      |
| 185 | D0F0x7C: IOC Configuration Control                  | 205 | D0F0xE4_x0[220,123:120]_000[2:1]: Phy Impedance Control                               |
| 186 | D0F0x84: Link Arbitration                           | 206 | D0F0xE4_x0[220,123:120]_000[C:B]: Phy Serial Bus Packet Control                       |
| 186 | D0F0x90: Northbridge Top of Memory                  | 208 | D0F0xE4_x0[220,123:120]_[5:4][7:6,3:0][8,0]2: Phy Receiver Phase Loop Filter Control  |
| 186 | D0F0x94: Northbridge ORB Configuration Offset       | 210 | D0F0xE4_x0[220,123:120]_[5:4][7:6,3:0][8,0]5: Phy Receiver Timing Margin Test         |
